Abstract

Purpose of Review To identify strategies for communicating with youth and children pre- and post-disaster in the context of a broader survey of child participation in disaster risk reduction as well as methods for communication with children.

Recent Findings Youth and children are capable of peer and community education and activism concerning disaster issues and such participation benefits the young actors. Family and sibling support are important in easing the impact of trauma on children. Contemporary forms of psychological first aid appear to do no harm and in line with current evidence. Generally, more evidence from evaluations is necessary to guide the development of communication strategies.

Summary Children are growing up in increasingly urban environments with less contact with nature and greater reliance on techno-social systems. Thus, young people may misunderstand natural hazards. Schools and conscious parenting can play important roles in building understanding and psychological resilience.

Keywords Child-centered disaster risk reduction · Child participation · Peer education · Disaster education · Family support · Psychological first aid

Introduction

Children are increasingly exposed to unpredictable disaster events that create significant consequences for their physical, psychological, emotional, and social health, which can in turn affect developmental trajectories and extend into adulthood. They are being born into an ever more complex world where the built environment and its surrounding “nature” is a second nature, engineered or unintentionally modified by human activity. The ensuing loss in access to natural environment can have consequences for children’s development and their

understanding of how their relationship with the natural environment affects their exposure to hazards [1, 2]: due to such misunderstanding, a child in Scotland resisted flood evacuation due to fear of sharks in the dark flood waters [3].

Children are growing up in a new era of earth history: the Anthropocene. This techno-social world is more hazardous due to many compounding changes. Urbanization, climate change, economic globalization, inequality, and austerity interact in complex ways. The home, school, and neighborhood can no longer be considered “safe.” Though never isolated from the impact of hazards and failed infrastructure, increasingly home, family, neighborhood, and community are increasingly less self-reliant and resilient.

The purpose of this review is to explore how best to communicate with children and families about the range of hazards that could disrupt their lives and how to be pro-active in age-appropriate ways to protect themselves and those around them. Communication modalities, content, and situation will differ according to the temporal framing or disaster stage. Communication beforehand, with a view to reducing potential impacts and becoming prepared, will differ from communication during the warning, evacuation, immediate response, relief, and recovery stages. The challenge is to communicate in a manner that does not merely transmit

This article is part of the Topical Collection on *Child and Family Disaster Psychiatry*

Q1

59 information or give instruction, but also facilitates commu- 109
 60 nication among family members and within a neighborhood 110
 61 or community. Preparedness for disruption, loss or displace- 111
 62 ment, and resilience in the face of such impacts requires co- 112
 63 production of strategies and collective action involving chil- 113
 64 dren, families, communities, civil society organizations, and 114
 65 local government. In this context, children should and can be 115
 66 empowered to participate as agents of change. The review 116
 67 also discusses recent literature on how best to communicate 117
 68 with children without producing anxiety and strategies that 118
 69 have been developed for lay people and professionals to 119
 70 communicate with children who have experienced disaster- 120
 71 related trauma and loss. 121

72 While there is currently no overarching agreement on either 122
 73 theory or intervention strategies for working with children, it 123
 74 is increasingly evident that theory and intervention strategy 124
 75 development should include not only the child but also the 125
 76 family and the school as well as the wider socio-cultural con- 126
 77 text and environmental settings in which interaction regularly 127
 78 occurs [4, 5, 6, 7]. The dynamic interaction across these 128
 79 domains will affect the development and application of adap- 129
 80 tive capacity and the rate and quality of response to disaster. 130
 81 Furthermore, the development of these frameworks should 131
 82 adopt child-centered approaches that acknowledge the funda- 132
 83 mental right of children to have agency in their own lives [4, 133
 84 5, 8], with this approach being better suited to understanding 134
 85 and addressing social justice issues and to exploring strategies 135
 86 to empower children, such as by adopting a citizenship in 136
 87 action approach [4]. 137

88 Communicating With Children

89 Communication with children should not be one-way. 138
 90 Children have perceptions and ideas and should be interlocu- 139
 91 tors, not the object of top-down instruction. Roger Hart was 140
 92 one of the first to lay out systematically an approach to treating 141
 93 children and youth as agents and participants in understanding 142
 94 and planning their surroundings [9]. His work was taken on 143
 95 board by UNICEF [10] and became much used, as he ob- 144
 96 served in a retrospective essay [11]. UNICEF developed this 145
 97 participatory approach to working with children as did the 146
 98 “Child in the City” project [12, 13]. Participatory work with 147
 99 children must be voluntary and personal, as well as interactive 148
 100 and responsive. These four adjectives are at the core of ethical 149
 101 considerations in communicating with children however they 150
 102 are chosen and whatever formal, professional ethics protocols 151
 103 are used [14]. Furthermore, Lundy [15] asserts that children’s 152
 104 participation is implied by the UN Convention on the Rights 153
 105 of the Child. 154

106 It is important to listen to children and youth where there 155
 107 may not be a formal setting or forum such as a school. The 156
 108 gender of children and youth is often overlooked in well-

intentioned efforts at listening. The Inter-Agency Standing 109
 Committee, the international reference group for humanitarian 110
 assistance, published the second edition of its *Gender* 111
Handbook for Humanitarian Action [16]. This very valuable 112
 resource has discussions of children and youth incorporated 113
 into its sections on “Needs Assessment” (pp. 30–43), 114
 “Participation” (pp. 84–87), “Education” (pp. 168–197), and 115
 “Protection” (pp. 298–323). In addition, the international non- 116
 governmental organization, PLAN International has pub- 117
 lished a thorough report on adolescent girls in disaster and 118
 refugee camp situations [17]. Fothergill and Peek [18] 119
 followed 650 children after Hurricane Katrina. The long an- 120
 nex in this book on methodology is an extremely useful guide 121
 to putting compassion into practice in discussing disasters 122
 with children and youth. 123

Communicating With Children in School

124 Depending on age, level of social-cognitive development, 125
 level of literacy, and access to materials and technology, 126
 many methods and media may be used to communicate with 127
 children and to co-produce knowledge of hazards and ways 128
 to reduce risk. Kitagawa [19] places disaster education in 129
 the broader context of safety training as these have evolved 130
 in Japan over the past few decades. One method of note that 131
 arose in Japan and has spread elsewhere is “town- 132
 watching.” This is an exercise in which children physically 133
 walk through the built environment with guides and discuss 134
 and later map and write about hazards as risk reduction. This 135
 method is based on earlier attempts in the 1960s and 1970s 136
 to democratize the government’s formerly top-down phys- 137
 ical planning [20], was adopted during the reconstruction of 138
 Kobe after the 1995 earthquake [21], and continues to be 139
 widely used in Japan [22]. Town-watching has broadened to 140
 include mountain-watching and coast-watching and has in- 141
 spired international guidelines provided by the UN 142
 Secretariat for Disaster Reduction [23] and similar ap- 143
 proaches in Vietnam, Malaysia, India, China, and Taiwan 144
 [24]. In addition, comic books, board games, video games, 145
 three-dimensional mapping, and many other methods and 146
 media are applicable [25–27]. 147

Children and Youth as Communicators and Actors

148 The Sendai Framework for Disaster Risk Reduction 2015– 149
 2030 [28] calls for the involvement of children and youth in 150
 planning for disaster risk reduction: 151
 152

Children and youth are agents of change and should be 153
 given the space and modalities to contribute to disaster 154
 155

156 risk reduction, in accordance with legislation, national
157 practice and educational curricula... (p. 23).

158 Children and youth play an important role in bringing di-
159 saster risk awareness home with them from school, encourag-
160 ing their families to make plans and take preparedness, and
161 communicating more widely in their communities [29, 30].
162 Two examples are a training program called Teen SERT that
163 has been developed for US high schools and flood activism in
164 England. SERT teaches basic skills such as light fire suppress-
165 sion, light search and rescue, first aid, transportation of the
166 injured, communication, and leadership, similar to the curric-
167 ulum of Community Emergency Response Training (CERT)
168 common in many parts of the USA [31]. Thus, school-based
169 training may be applied in the community. Mort and col-
170 leagues studied flood-affected youth in England [32], identi-
171 fying ways that they could be better supported and also how
172 their experience can help to shape flood management policy.
173 The youth themselves wrote a “Manifesto” asserting the im-
174 portance of including youth in planning and pointing out their
175 previous absence. Fothergill cites a number of cases in which
176 youth have been directly engaged in relief and recovery [33].

177 Ronan and co-authors review a large number of child-
178 centered disaster risk reduction and resilience (CC-DRR) pro-
179 grams [34]. Another review of youth participation as well as
180 disaster education in schools concluded that the former tended
181 to focus more deeply on the root causes of disaster than
182 school-based programs and continued with the following rec-
183 ommendation [35, p. 8]:

184 Notably, several of the papers on children’s participation
185 in DRR [disaster risk reduction] were published as a
186 result of collaborations between NGOs and academia.
187 From this perspective, new tools and approaches have
188 emerged in CCDRR [child centred disaster risk reduc-
189 tion] practices and evidence on the impact of children’s
190 participation documented. Due to these positive out-
191 comes, it is recommended that this type of collaboration
192 should be maintained and replicated to deliver more
193 positive outcomes for children that are conducted direct-
194 ly with those who deliver a large percentage of the pro-
195 grams, e.g. NGOs.

197 A recent review of literature on child and youth participa-
198 tion in disaster management concludes that besides social and
199 educational benefits young people’s activities can have a
200 range of positive psychological benefits [36, p. 5]:

202 Participation yields numerous potential benefits for chil-
203 dren, including enhanced personal development and
204 skills, self-efficacy, and interpersonal relationships, and
205 for communities through improved social connections
206 and networks and disaster preparedness.

**Communicating With Children and Families
in Post-disaster Situations** 207
208

209 Regarding recovery settings, [4] highlights how the strategies
210 adopted by schools can be diverse. They include *child-at-risk*
211 (child as victim and passive and in need of protection, poten-
212 tially including emotional contagion from family settings,
213 child insulated from community settings/involvement, remov-
214 al from disaster context, no or minimal discussion of disaster
215 at home, parents discouraging discussion of disaster), *devel-*
216 *oping child* (schools adopted a participatory, developing-child
217 approach and provided diverse strategies for students to pro-
218 cess experiences, creating a sense of shared fate and facilitated
219 putting the events into a wider (development and social) con-
220 text [8], and *citizen child* (develop capacity and opportunity to
221 empower students by facilitating collective action in ways
222 consistent with social justice) approaches.

Family Support 223

224 The potential for disasters to create prolonged disruptions to
225 family and support networks can produce repercussions
226 throughout childhood development and on into adult lives
227 [37]. However, not all impacts have negative consequences
228 [38], and not all children are overwhelmed by disasters [39].
229 Neither children’s exposure, nor their reactions to disasters are
230 homogenous, and this needs to be considered when concep-
231 tualizing and researching children’s adaptive capacity and re-
232 siliance [40]. The variation in children’s reactions to disasters
233 and the limited research focused on children’s own experi-
234 ences introduces the need for a more detailed assessment of
235 children’s experiences of coping and how their positive and
236 negative adaptations are influenced by their social ecological
237 contexts (e.g., family dynamics).

238 Mooney et al. (in prep) identified multiple resources in the
239 children’s immediate family context of parents, siblings, ex-
240 tended family, and pets that appeared fundamental to their
241 capacity to cope and adapt. They reported that children were
242 enabled by others’ effective coping and coping assistance,
243 protection, reassurance, and re-establishment of routines and
244 stability fostered children’s adaptive behaviors. Parenting that
245 was flexible and sensitive to children’s changing needs was
246 found to scaffold children’s capacity to cope with earthquake
247 events and consequences. Their findings support arguments
248 that family relationships, particularly parental relationships,
249 facilitate children’s capacity to cope effectively with a disaster
250 and suggest the importance of interventions that support par-
251 enting and family endeavors during a post-disaster period. In
252 this context, parents can both help and hinder their child’s
253 post-disaster coping (Table 1).

254 Children, especially younger children, look to their parents
255 for cues of how to act. How parents function before, during,
256 and after the disaster has significant influence on how children

Table 1 From Mooney et al., in prep (*Parental Influence on Coping and Adaptation*)

Parental role in <i>supporting</i> effective coping and adaptation	Parental role in <i>inhibition</i> of effective coping and adaptation
<ul style="list-style-type: none"> • Coping assistance through modeling, coaching, and teaching <i>effective</i> coping • Protection, buffering, reassurance • Increased parental awareness: watchful awareness, acceptance of disaster-related changes in behavior, positive appraisal, and active involvement of child in disaster response/preparation • Providing stability, routines, and distraction so as to “get on” 	<ul style="list-style-type: none"> • Coping assistance through modeling, coaching, and teaching <i>ineffective</i> coping such as withdrawal and ineffective emotional regulation (e.g., panic) • Lack of coping assistance • Lack of protection, buffering, reassurance • Overprotection • Limited parental awareness of child’s feelings, disaster-related behavior, or needs • Over-watchful awareness mainly focused on detecting trauma symptoms • Inability to get on, or provide sufficient stability, routines, or distraction

257 respond [41]. Knowledge of just how family elements in the
 258 children’s immediate context support effective coping is lim-
 259 ited [6].

260 Studies investigating children’s experience from their own
 261 reports are rare [42]. Most of the research with children is
 262 about them or for them, rather than with them. Nevertheless,
 263 research suggests that children can be articulate and informed
 264 participants [4•]. There is a need for research that listens to
 265 children’s own voices [43].

266 Research suggests that children’s resources and external
 267 elements promoting resilience (e.g., parent’s coping assis-
 268 tance) can interact in a cumulative or additive manner [44].
 269 Coping socialization occurs throughout childhood, but a di-
 270 saster situation creates complex demands that present multiple
 271 possibilities for coping assistance from parents [45]. This as-
 272 sistance can occur through modeling. In the interactive parent/
 273 child relationship, many parents model a calm response to
 274 earthquakes and used problem-solving to manage conse-
 275 quences [5].

276 Children who are helped by their parents in ways that fa-
 277 cilitate their ability to process information about disaster ex-
 278 perience have better adjustment [46] and are more able to use
 279 coping strategies when they perceive such help is available to
 280 them. Parents who are more aware of their children’s needs
 281 enhance capacity in the children to adapt after disaster [41].
 282 However, some parents underestimate the distress of children
 283 in post-disaster situations [47] or do not seek assistance from
 284 professionals or peers when their children are experiencing
 285 distress [48].

286 Parental assistance and responsiveness is affected by the
 287 level of well-being of parents. Parents experiencing high dis-
 288 tress are less able to re-establish stability, focus on moving
 289 forward, or offer support [49, 50]. However, if parents are
 290 coping well themselves, this can, by teaching or modeling
 291 effective coping skills in a flexible way, and by maintaining
 292 equilibrium through routine and regulation, facilitate chil-
 293 dren’s capacity to adapt following disaster [51•]. In doing

so, they re-establish a sense of safety and calming, encourage
 self-efficacy and connectedness, and provide hope that chil-
 dren and family could one day “get on” from the disaster.

McNeill and Ronan [52] examined whether family consti-
 tution, particularly regarding the presence of children of dif-
 ferent (very young, young, or teenage children) ages, influ-
 enced disaster preparedness. They found that households with
 young (under twelve years old) and very young (under six
 years old) children prepared less for wildfires compared with
 their childless counterparts at the start of the wildfire season,
 but they had caught up in property preparedness by the end of
 it. Households with younger children performed fewer
 disaster-planning actions than childless households. More-
 over, they reported lower motivation to prepare, greater
 perceived difficulty in preparing, and having less time to pre-
 pare than childless households. They discussed how these
 findings reflect the younger age of the adult parents rather than
 the presence of younger children per se.

Findings support research highlighting the importance of
 secure attachment relationships for children [53], and that the
 experience of disaster may increase the bonds in the family
 system [54], when the family system is functioning well in the
 disaster context. The family and parents within the family
 system is a key in fostering their children’s responses (e.g.,
 [55]). This signals the importance of interventions to support
 parenting endeavors during a challenging disaster period. As
 parents’ capacities to support their children appear connected
 to their own stress level, it is important to provide supportive
 interventions to parents in a difficult situation and target addi-
 tional support to those parents who are highly affected by the
 disaster situation. Other members of the family, for example
 siblings, also appeared to affect the children’s coping and
 adaptation.

Sibling relationships can affect disaster experience in a
 positive or negative way [5]. With siblings, children could
 observe a diverse range of responses. Siblings acted as a po-
 tential source of mutual support when the family was

331 functioning effectively as a group system and siblings could
 332 “stand-in” for absent parents. Hakvoort and co-authors [56]
 333 report on the compensatory effect of one warm supportive
 334 relationship, such as a sibling relationship, which can have a
 335 positive spill-over effect onto other relationships within a fam-
 336 ily system.

337 Carpenter and others [57] examined event-related house-
 338 hold discussions among area families ($N=460$, ages 4–19)
 339 during the 2013 Boston Marathon bombing and subsequent
 340 shelter-in-place warning, as well as links between types of
 341 household discussions and child post-traumatic stress (PTS).
 342 Results generally endorse the importance of open, reassuring,
 343 and reciprocal communication with caregivers. Alternatively,
 344 avoiding event-related discussion around children, and not
 345 reassuring their safety was associated with adverse outcomes.
 346 Among results, the authors found:

- 347 • There was considerable heterogeneity in household
 348 discussions.
- 349 • After controlling for child’s direct exposure to the poten-
 350 tially traumatic attack/manhunt events, children showed
 351 lower PTS when it was their caregivers who informed
 352 them about the attack and manhunt, and when their care-
 353 givers expressed confidence in their safety and discussed
 354 their own feelings about the manhunt with their child.
- 355 • Children showed higher PTS when their caregivers did not
 356 discuss the events in front of them, asked others to avoid
 357 discussing the events in front of them, and expressed con-
 358 cern at the time that their child might not be safe.
- 359 • Child age and traumatic attack/manhunt exposure moder-
 360 ated several links between household discussions and
 361 child PTS.

362 Similar results were found by [47] in a cross-national
 363 review of family and social factors that influence children’s
 364 reactions to different types of disasters. Although some of
 365 the identified factors do not directly address the topic of
 366 “communication with children and families in post-
 367 disaster situations,” many are likely to have some bearing
 368 on communication. For example, positive maternal-child
 369 relationship offset adverse outcomes in adolescents (Sri
 370 Lanka tsunami impact, 2004); child-parent conflict contrib-
 371 uted to increased post-traumatic stress disorder ((PTSD)
 372 Hurricane Katrina, 2005); and parents supporting coping
 373 strategies led to less adolescent distress and vice versa
 374 (September 11th Attack, 2001). Child’s perception of at-
 375 tachment to mothers and perceptions of mothers parenting
 376 style influenced child anxiety (Hurricane Katrina); parental
 377 support for maintaining routines linked to better outcomes
 378 while parental restrictions linked to greater functional im-
 379 pairment and PTSD symptoms (Israeli adolescents exposed
 380 to terrorism); evidence for cultural differences in influence
 381 of parenting style (e.g., authoritarian and permissive

maternal parenting styles linked to greater distress in 382
 Jewish children, but benefitted Arab children). The remain- 383
 ing discussion focuses on social factors, especially the neg- 384
 ative effect of disaster-related media exposure. Child peer 385
 support has a protective role (Hurricane Katrina). There are 386
 also benefits of providing social support to others 387
 (21 months after a flood in a Polish town). High school 388
 support buffered the relationship of witnessing community 389
 and terrorist violence with violent behavior (Israeli 390
 adolescents). 391

Research in countries where pets are part of the family 392
 culture, as in the present study context, has suggested that loss 393
 of pets may affect children’s response and recovery from di- 394
 sasters [38], and suggested the importance of the animal- 395
 human bond, demonstrated by the number of people who 396
 refuse to evacuate during a disaster if they cannot take their 397
 pet [58]. 398

Psychological First Aid 399

Trethowan and Nursey [59] review a two-phase intervention 400
 program designed to provide schoolteachers with knowledge 401
 and skills to help young people recover in the wake of the 402
 devastating 2009 Victorian bushfires. After consulting child 403
 and adolescent trauma experts and the Department of Health 404
 and Human Services, the Victorian Department of Education 405
 adapted two US programs to train teachers in child support 406
 and recovery following a disaster. This resulted in a two-phase 407
 program. The first was “Psychological First Aid and Mental 408
 Health First Aid: A Guide for Teachers.” This was delivered in 409
 face-to-face training sessions to teachers in bushfire-affected 410
 regions. Training emphasized to teachers that some children 411
 will need more help than they can provide and that their role is 412
 not to replace mental health professionals. Phase 2 involved 413
 online delivery of “Skills for Psychological Recovery” de- 414
 signed as a classroom teaching aid to foster resilience and 415
 coping skills. Programs were tailored to different age levels. 416
 Teachers were encouraged to maintain appropriate boundaries 417
 and reminded that their role should not constitute a counseling 418
 role. They were trained to identify young people at high risk 419
 and needing professional support, and they were encouraged 420
 to involve parents. This online material has been available 421
 online to all primary and secondary schools in Victoria since 422
 late 2012 and had been completed by four hundred teachers as 423
 of October 2015. The authors conclude by recommending a 424
 “systematic roll out and evaluation of the program’s capacity 425
 to successfully support teachers, children and adolescents in 426
 the post-recovery period” [59, p. 20]. 427

Eifling and Moy [60] provide an evocative article reviewing 428
 the current evidence base (as of 2015) for the use of psycholog- 429
 ical first aid (PFA) during disaster response. The authors begin 430
 by pointing to the number of historical examples where post- 431
 traumatic responses have been medically misunderstood (e.g., 432

433 soldiers heart, shell shock). They go on to explain how critical
 434 incident stress debriefing emerged during the cold war era,
 435 which went on to become a dominant model of care offered
 436 following trauma, until research established that it was unhelp-
 437 ful and ultimately increased the one-year risk of PTSD follow-
 438 ing trauma. In their review of the evidence for PFA, the authors
 439 identified three high-quality systematic reviews, the most re-
 440 cent one being by Dieltjens and colleagues [61•]. None of these
 441 reviews were able to identify any rigorous trials with clear evi-
 442 dence for or against the use of PFA. The author’s note that this
 443 lack of experimental evidence is “extraordinary” when consid-
 444 ering how prominently PFA features in many international
 445 guidelines. Rather than experimental evidence, the authors find
 446 that “the whole family of PFA guidelines” is based “on the
 447 wealth of psychological and neurobiological science” and
 448 therefore such guidelines “seem reasonable, reality-driven and
 449 worthwhile” [60, p. 34].

450 Vernberg and colleagues [62] discuss how strategies for
 451 positive psychology can be used to improve mental health
 452 outcomes for children and adolescents during all stages of
 453 disaster preparedness, crisis response, and recovery. It iden-
 454 tifies three important developmental considerations for posi-
 455 tive psychology application: (1) using of age-appropriate
 456 language and concepts (e.g., consider reading level for pre-
 457 sented material); (2) addressing typical age-related needs
 458 and concerns (e.g., needs of toddler vs. adolescences); and
 459 (3) employing positive psychology strategies in naturally
 460 occurring and developmentally relevant settings (e.g., im-
 461 portance of school). The authors go on to explain in rather
 462 general terms how positive psychology can be infused into
 463 “5 Essential Elements of Disaster Mental Health” (cf. [63]),
 464 which they list as (1) promotion of a psychological sense of
 465 safety; (2) promotion of calm; (3) promotion of a sense of
 466 self-efficacy and collective efficacy; (4) promotion of con-
 467 nectedness; and (5) instilling hope. They finish with two
 468 interesting case studies demonstrating the use of such
 469 strategies.

470 Pfefferbaum’s team [64•] provided a review of post-
 471 disaster interventions and found that no empirical studies
 472 of psychological first aid delivered early in the post-
 473 disaster phase can be identified. Very few mental health
 474 interventions for children in the early post-disaster phase
 475 have been evaluated. Interventions within three months of
 476 the event were included in the review. Eleven publications
 477 met inclusion criteria, four of which were randomized con-
 478 trol trials. Sixteen interventions were implemented in the
 479 eleven selected publications. Interventions included cogni-
 480 tive behavioral therapy, narrative exposure, meditation re-
 481 laxation, debriefing, and eye movement desensitization and
 482 reprocessing. Positive outcomes were noted for various out-
 483 comes including post-traumatic stress disorder cases and
 484 post-traumatic stress symptoms, depression, anxiety, and
 485 functioning.

Conclusion

486

487 As most disaster research has focused on children’s trauma
 488 and symptomology, rather than on investigating processes
 489 that enable children to respond adaptively within their so-
 490 cial and environmental contexts, our understanding of how
 491 children cope effectively and adapt well to disasters is in-
 492 complete and an infrequently researched area [47]. While it
 493 is evident that many children can demonstrate positive
 494 adaptive outcomes when facing adversity [65], neither the
 495 specific underlying processes nor how their ecological con-
 496 texts (e.g., family, peers, school) interact over time to influ-
 497 ence coping and adaptive processes are well understood. To
 498 this can be added a need to understand how growing up in
 499 the Anthropocene is likely to affect children. More work is
 500 needed to understand two implications in particular of
 501 growing up in cities during this period of Earth history:
 502 growing separation from nature and exposure to urban en-
 503 vironmental hazards. More research is also needed on how
 504 children actively contribute to disaster risk reduction and
 505 response. We can learn from the town/mountain/coast-
 506 watching examples discussed above to highlight a need to
 507 include interacting in the natural environment and its impli-
 508 cations for well-being and environmental cognition in fu-
 509 ture work. To understand positive adaptation, it is as impor-
 510 tant to examine elements that support positive adaptation as
 511 it is to investigate trajectories towards negative adaption and
 512 psychopathology [66].

513 Coping research is still evolving and has yet to conceptu-
 514 alize a developmental framework for children’s coping, or to
 515 fully develop a model of children’s coping within disasters
 516 [47]. Children’s coping capacities depend in part on the re-
 517 sources available to them (e.g., [67]). These may be internal
 518 (e.g., self-efficacy) or external (e.g., family systems, social
 519 support networks) resources in the children’s contexts.
 520 Children are dependent on and interact in space and time with
 521 the proximal systems operating in their social and physical
 522 environment [68], developing resiliency processes while
 523 nested within their cultural context of multiple proximal ecol-
 524 ogies: family, school, and neighborhood [5, 7•]. Children’s
 525 capacities to adapt and cope are thus affected by the contexts
 526 in which their development occurs. Of primary importance are
 527 the children’s family systems and their relationships with their
 528 parents.
