1 INTRODUCTION

In 1992 the Rannoch Trust established the Loch Laidon catchment land-use experiment, which is investigating the effects of summer cattle grazing on the terrestrial and aquatic upland environment. Situated in Perthshire, Scotland, the study area falls within a number of designations, including the Rannoch Moor Special Area of Conservation and Site of Special Scientific Interest, the Rannoch Lochs Special Protection Area and the Tayside Local Biodiversity Action Plan.

The project presented and summarised here comprises the aquatic monitoring element of the experiment. Allott *et al* (1994) described the project rationale and background whilst progress reports (Monteith *et al.* 1995;Monteith *et al.* 1996;Monteith *et al.* 1997;Monteith *et al.* 1999;Shilland *et al.* 2001;Shilland *et al.* 2003;Shilland *et al.* 2004;Shilland *et al.* 2005;Shilland *et al.* 2006;Shilland *et al.* 2007) as well as a conference proceeding (Shilland *et al.* 2008) have provided reviews of the accumulating chemical and biological datasets.

Results are presented for the entire monitoring period from 1992 to April 2010 and take the form of a data report. Further statistical analysis and interpretation will follow in a report due in December 2010.

2 DATA PRESENTATION

Data are held on a central Access database at the Environmental Change Research Centre (ECRC) and in this report are presented as raw data, graphs and summary statistics.

Selected water chemistry variables are presented as time series with values for two or three burns superimposed. Where appropriate, time series of the ratios of values for the Experimental and Control Burns are also overlaid. Common (natural) variability is thus controlled for. Any impact of grazing on water chemistry should be detected as a progressive departure from the normal distribution of the ratio (i.e. any deviation away from a horizontal line). Data are also presented for physical measurements of rainfall, stream temperature and stream height that commenced in November 2007.

The following biotic and diversity indices have been used for macroinvertebrates:

Hill's N1 approximates to the number of abundant species.

Hill's N2 approximates to the number of very abundant species in the sample.

Hill's E5 is a measure of the evenness of species occurrences in a sample. E5 approaches zero as a single species becomes more dominant in the community.

Richness (rareftn 100) predicts the expected number of taxa in a sample of 100 individuals.

BMWP is a scoring system for macroinvertebrates based on a scale of 1 to 10 given to each taxonomic family. It provides an indication of water quality by assigning families very sensitive to organic pollution a score of 10, whilst those that

thrive in organically polluted systems, such as bloodworms, are assigned a score of 0.

ASPT is the Average Score Per Taxon, based on the BMWP score divided by the number of taxa in the sample. A range of 6.3 to 6.7 is typical for a diverse fauna.

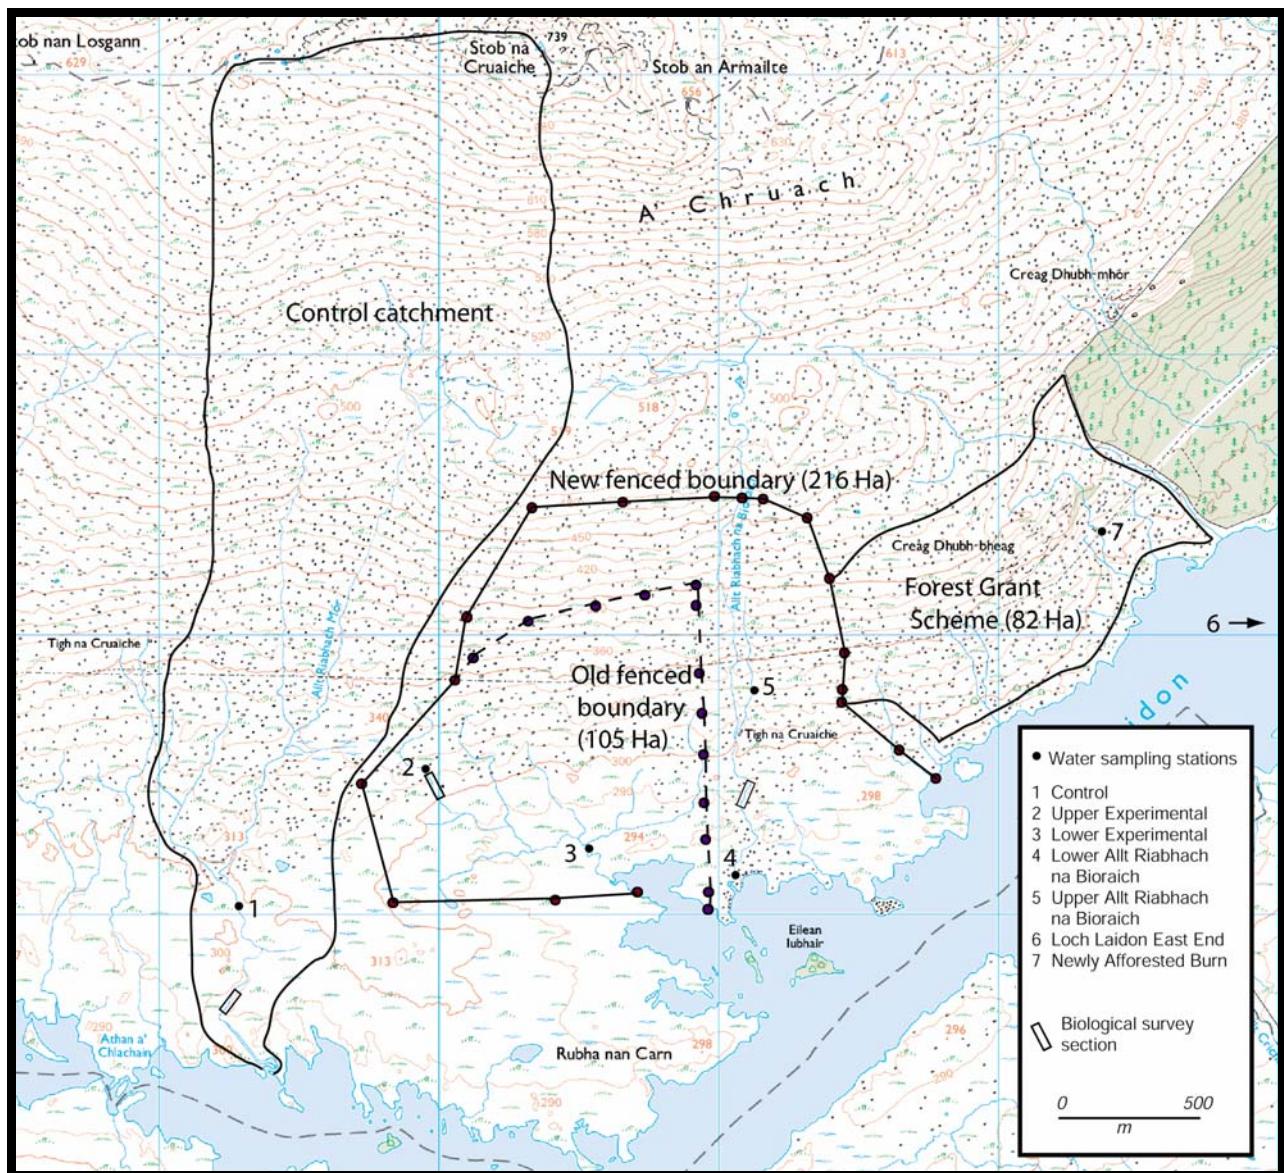

Diatom and aquatic macroinvertebrate diagrams show percentage abundances of individual species for each year of sampling. Macroinvertebrate species occurring with a minimum abundance of 1.5% are presented whereas the diatom graphs show species with a minimum abundance of 1%.

Fish densities for the three experimental streams are shown for both fry and parr, and are displayed as fish numbers per meter square.

In August 2009 a sediment core was taken from the bay of Loch Liadon into which the Experimental Burn flows. Core data presented include lithostratigraphic analyses of dry weight and loss on ignition, sediment spheroidal carbonaceous particle concentrations and a sediment diatom stratigraphy.
