10 **Fig. S1.** Resolution test for cases with different resolution, but otherwise the same parameters as
11 the reference case. A local grid refinement by up to 2 times near the surface and CMB (i.e., ~ 10
12 km radial grid spacing) is considered for all cases. Black line is the reference case with a
13 resolution of 1024×128 cells. Radial average profiles of basalt fraction (a) and total temperature
14 (b) from 0 to 25 Myr. Radial average profiles of basalt fraction (c) and total temperature (d) from
15 2 to 4.5 Gyr. Cases as labeled (The first and second numbers refer to the number of cells in the
16 horizontal and radial directions, respectively). Note that two cases did not run much longer than
17 25 Myr due to computational limitations. We demonstrate that four cases (1024×64 , 1024×128 ,
18 1024×256 , and 2048×256) have very similar basalt-fraction and temperature profiles, hence
19 confirming that the resolution used in our study is sufficient.

20 **Table S1.** Physical Parameters for Multicomponent Phase Changes. i and j are the indices for
 21 each relevant phase change.

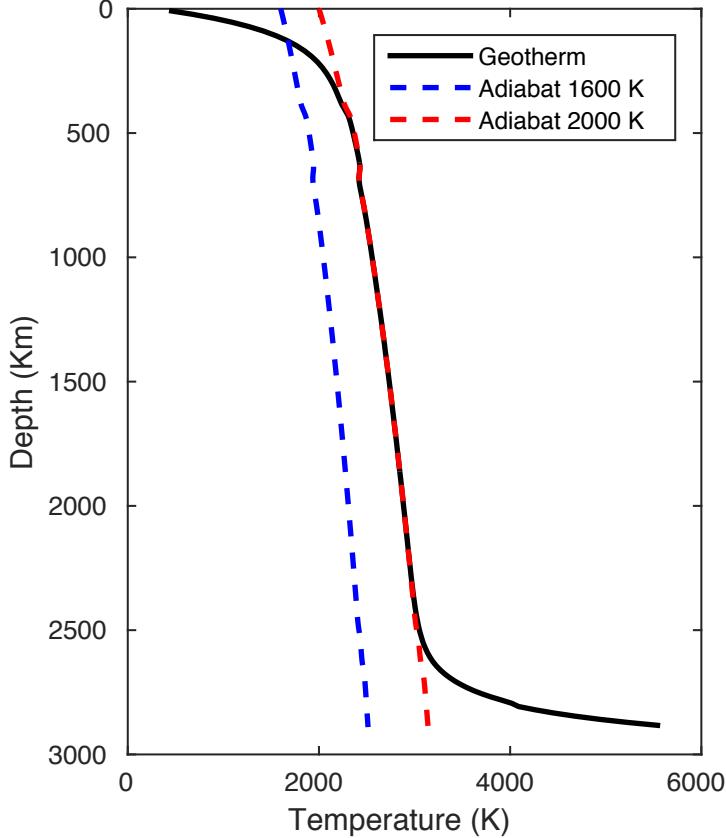

#	Depth (km)	Temperature (K)	$\Delta\rho_{ph}$ (kgm^{-3})	Γ_{ph} (MPa/K)	Width (km)
Olivine-Spinel-Perovskite-Postperovskite (system $i=1$)					
$j=1$	410	1600	280	2.1	29
$j=2$	660	1900	400	-1.8	29
$j=3$	2740	2650	62	7.2	29
Pyroxene-Garnet-Perovskite-Postperovskite (system $i=2$)					
$j=1$	60	0	350	0	29
$j=2$	300	1600	150	1.0	75
$j=3$	720	1900	500	0.7	75
$j=4$	2596	2560	62	7.2	29

32

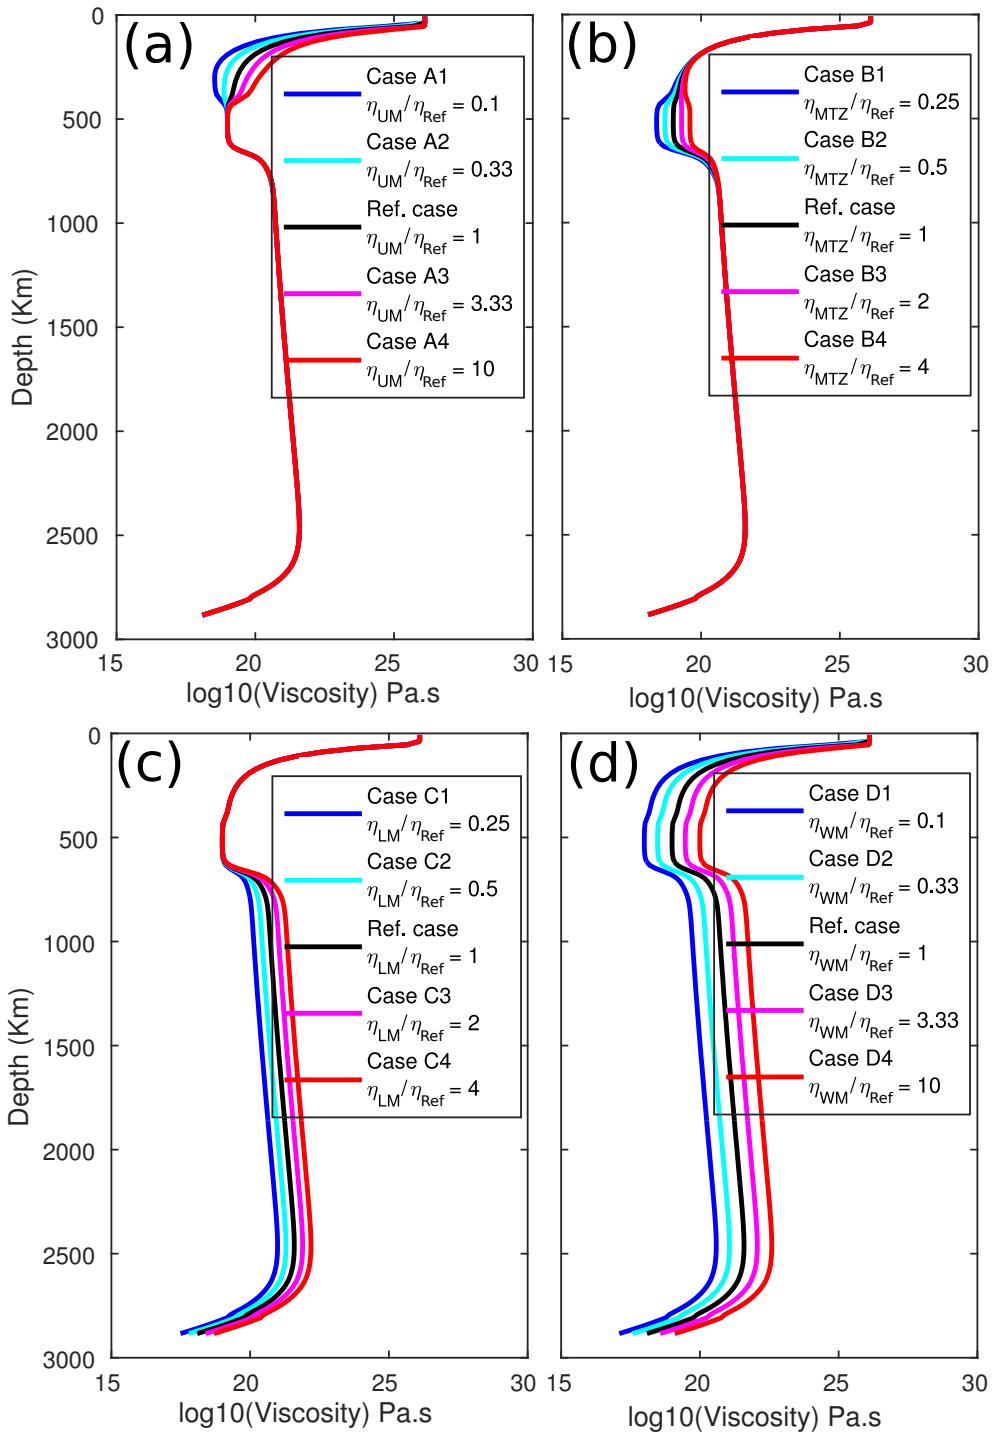

33 **Table S2.** Physical parameters of mantle model. Reference viscosity is defined along the
 34 reference adiabat with $T_a = 1600 K$. Note that (*) denotes free parameter in our models, where
 35 $1.29 \times 10^{20} \leq \eta_0 \leq 1.29 \times 10^{22}$, $0.005 \leq \mu \leq 0.08$, $0.125 \leq \lambda_{410} \leq 8$, $7.5 \leq \lambda_{660} \leq 120$ and $0.02 \leq$
 36 $X_{BS} \leq 0.35$; all other parameters are fixed. Dimensional values listed above are for the reference
 37 model.

Notation	Parameter	Dimensional Value
η_0	Reference viscosity*	$1.29 \times 10^{21} Pa s$
λ_{410}	Viscosity jump at 410 km*	1
λ_{660}	Viscosity jump at 660 km*	30
X_{BS}	Initial basalt fraction*	0.2
μ	Friction coefficient*	0.02
C	Cohesion coefficient at surface	$4.6 MPa$
D	Thickness of the mantle	$2890 km$
E	Activation energy	$2.87 \times 10^5 Jmol^{-1}$
V	Activation volume	$2.49 \times 10^{-6} m^3 mol^{-1}$
ρ_0	Reference (surface) density	$3300 kgm^{-3}$
g	Gravity	$9.8 m s^{-2}$
α_0	Reference (surface) thermal expansivity	$5 \times 10^{-5} K^{-1}$
k_0	Reference (surface) thermal conductivity	$3 Wm^{-1} K^{-1}$
κ_0	Reference (surface) thermal diffusivity	$7.58 \times 10^{-7} m^2 s^{-1}$
Di	Surface dissipation number	1.3
γ	Reference (surface) Gruneisen parameter	1.3
T_a	Reference adiabat	$1600 K$
ΔT_{sa}	Temperature scale	$2500 K$

57	T_s	Surface temperature	300 K
58	H_r	Initial internal heating rate	$1.58 \times 10^{-11}\text{ Wkg}^{-1}$
59	L_h	Latent heat of fusion	$6.0 \times 10^5\text{ Jkg}^{-1}$
60	τ	Half life of internal heating	2.24 Gyr

64 Fig. S2. Initial geotherm (i.e. real temperature profile) for all cases. Note that the initial geotherm
 65 is set to the 2000 K adiabat (red dashed line) across most of the mantle. In turn, physical
 66 properties (e.g., the density) are calculated along the 1600 K adiabat (blue dashed line) for all
 67 cases.

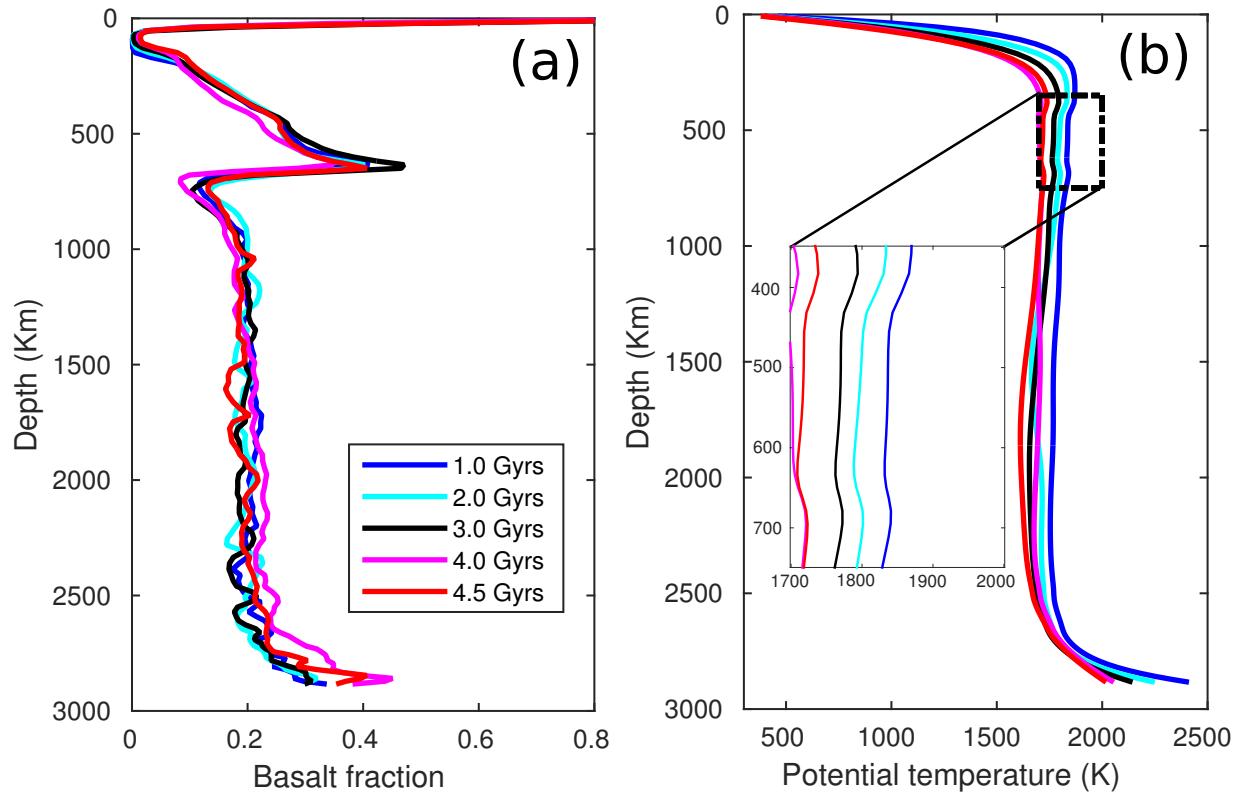

68

69 **Fig. S3.** Reference radial viscosity profiles for all cases in groups A-D as labeled. η_{UM} , η_{MTZ} ,70 η_{LM} and η_{WM} denote uppermost-mantle viscosity, MTZ viscosity, lower-mantle viscosity, and

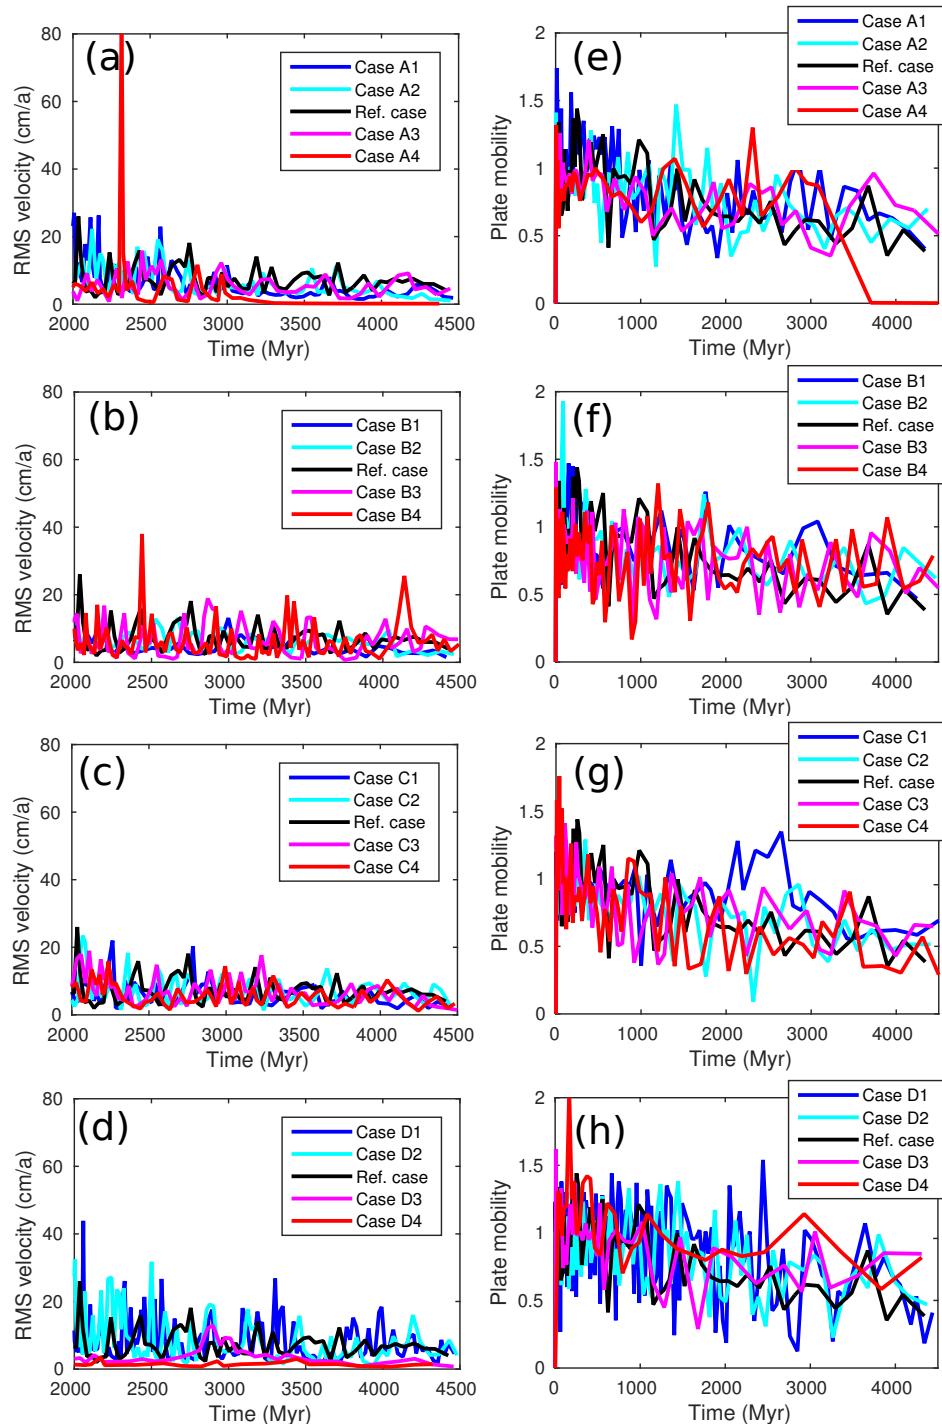

71 whole-mantle viscosity, respectively. Correspondingly, η_{Ref} denotes the viscosity of the reference

72 case.

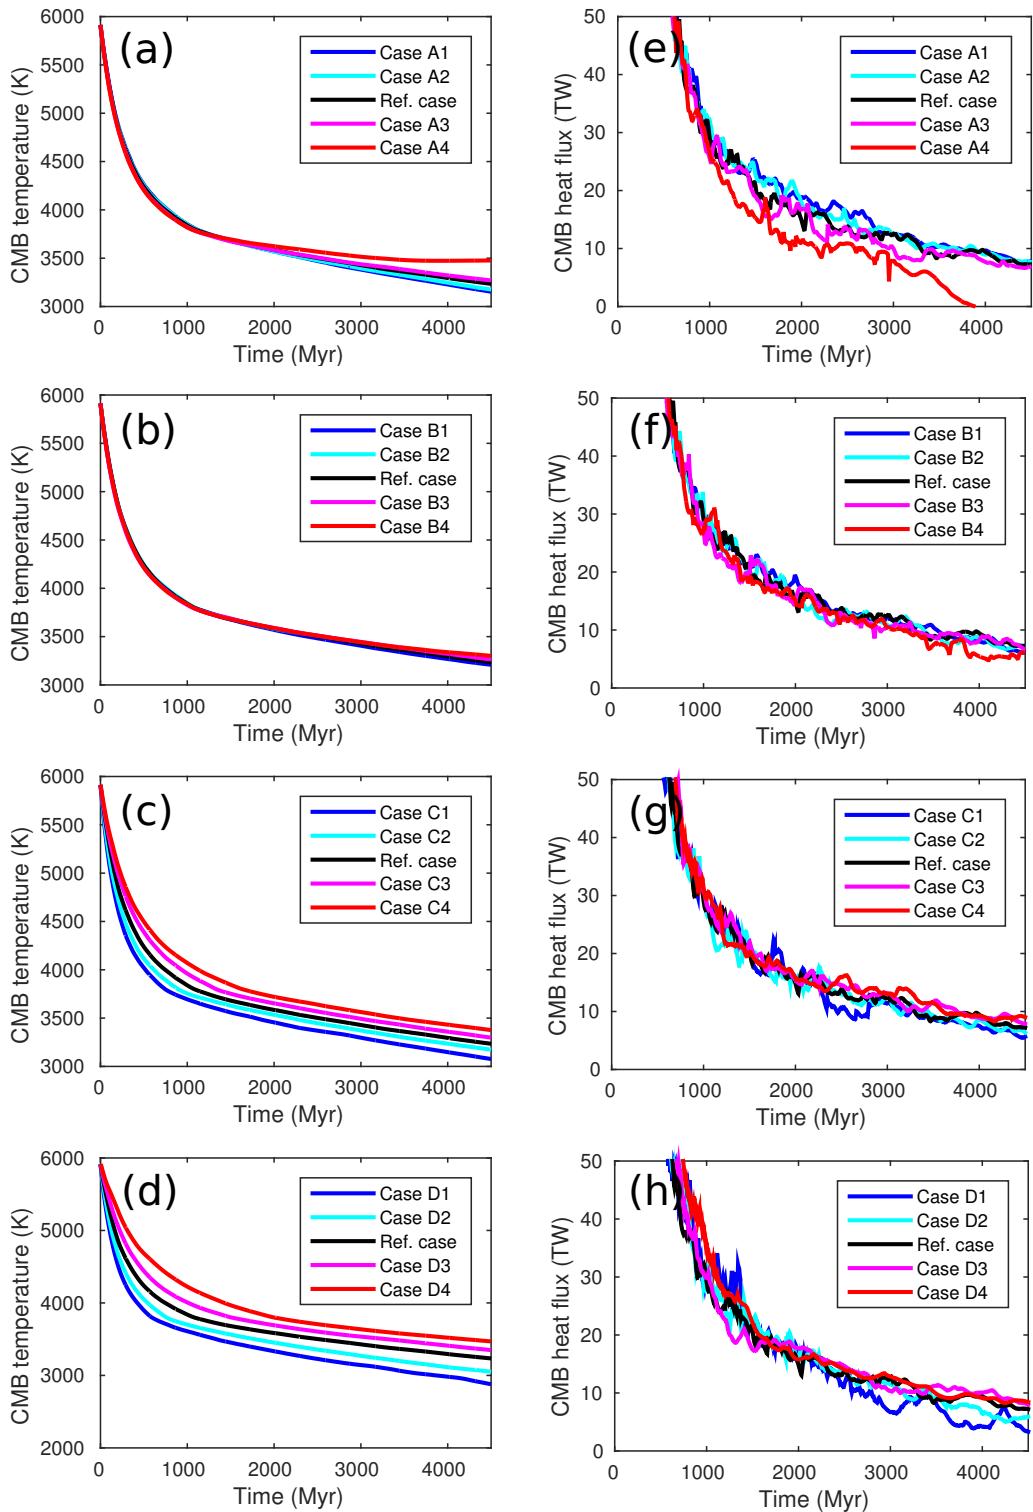

73
74 **Fig. S4.** Radial average profiles of (a) X_{BS} (compositional index) and (b) potential temperature
75 for a test case with a low initial internal heating rate ($H_r = 3.4 \times 10^{-12} Wkg^{-1}$, other parameters are
76 the same as those in the reference case) at different model times (from 1.0 to 4.5 Gyr as labeled).
77 Note that the predicted radial average profiles of X_{BS} are very similar to that of reference case,
78 but that predicted potential temperature is more realistic (see Fig. 3a-b in the text for
79 comparison). H_r in this test case is lower than estimated for the bulk Earth's mantle
80 (Lyubetskaya & Korenaga, J2007). However, this test case may mimic a situation, in which a

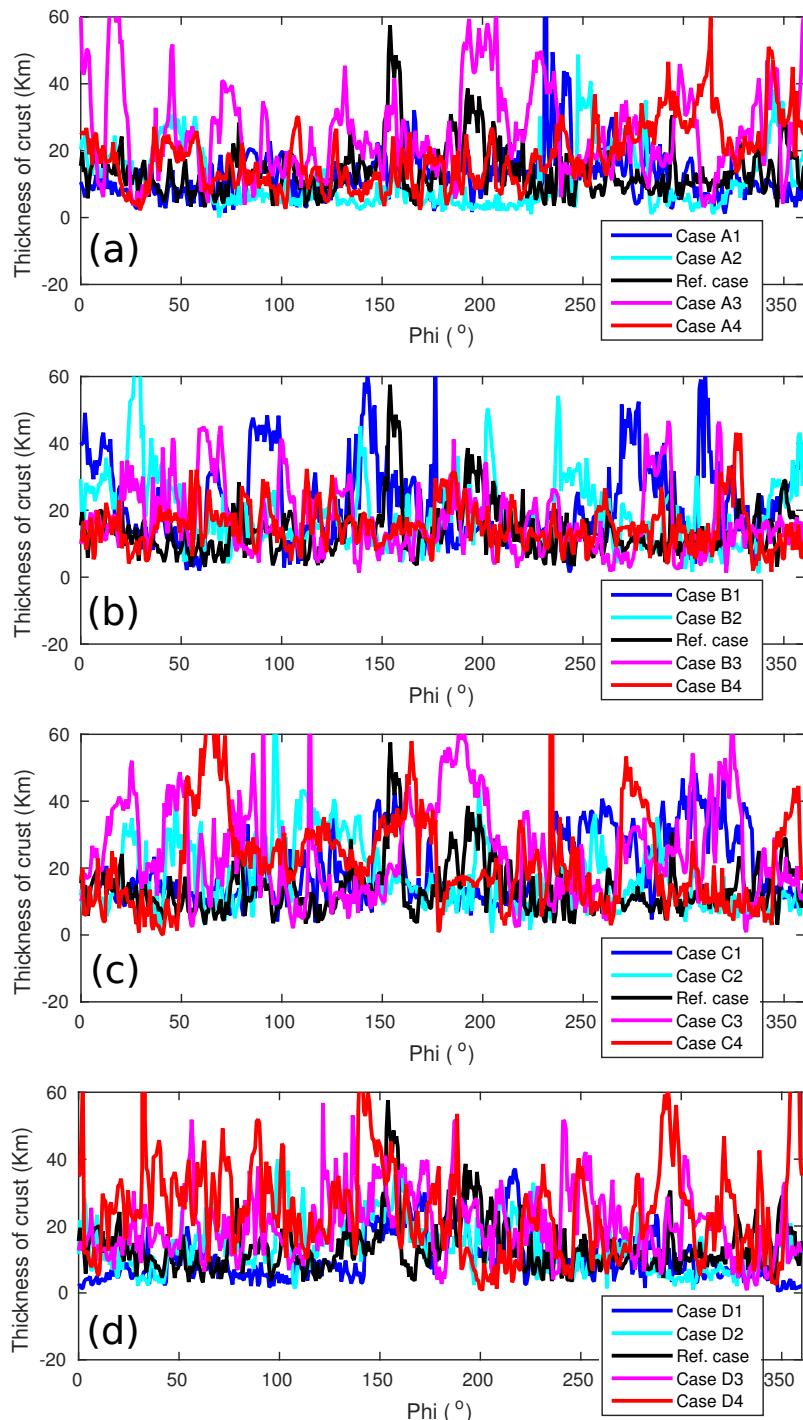

81 significant fractions of internal heat sources are stored near the CMB, e.g., due to partitioning of
 82 incompatible heat-producing elements into thermochemical piles. This interpretation is
 83 confirmed by Lourenço et al. (2018), see their Figure 1a-c.

85 **Fig. S5.** Properties used to quantify Earth-like plate tectonic behavior. Left row: root-mean-
86 square velocity of plates at the surface; right row: plate mobility as defined in Tackley (2000).
87 Cases as labeled.

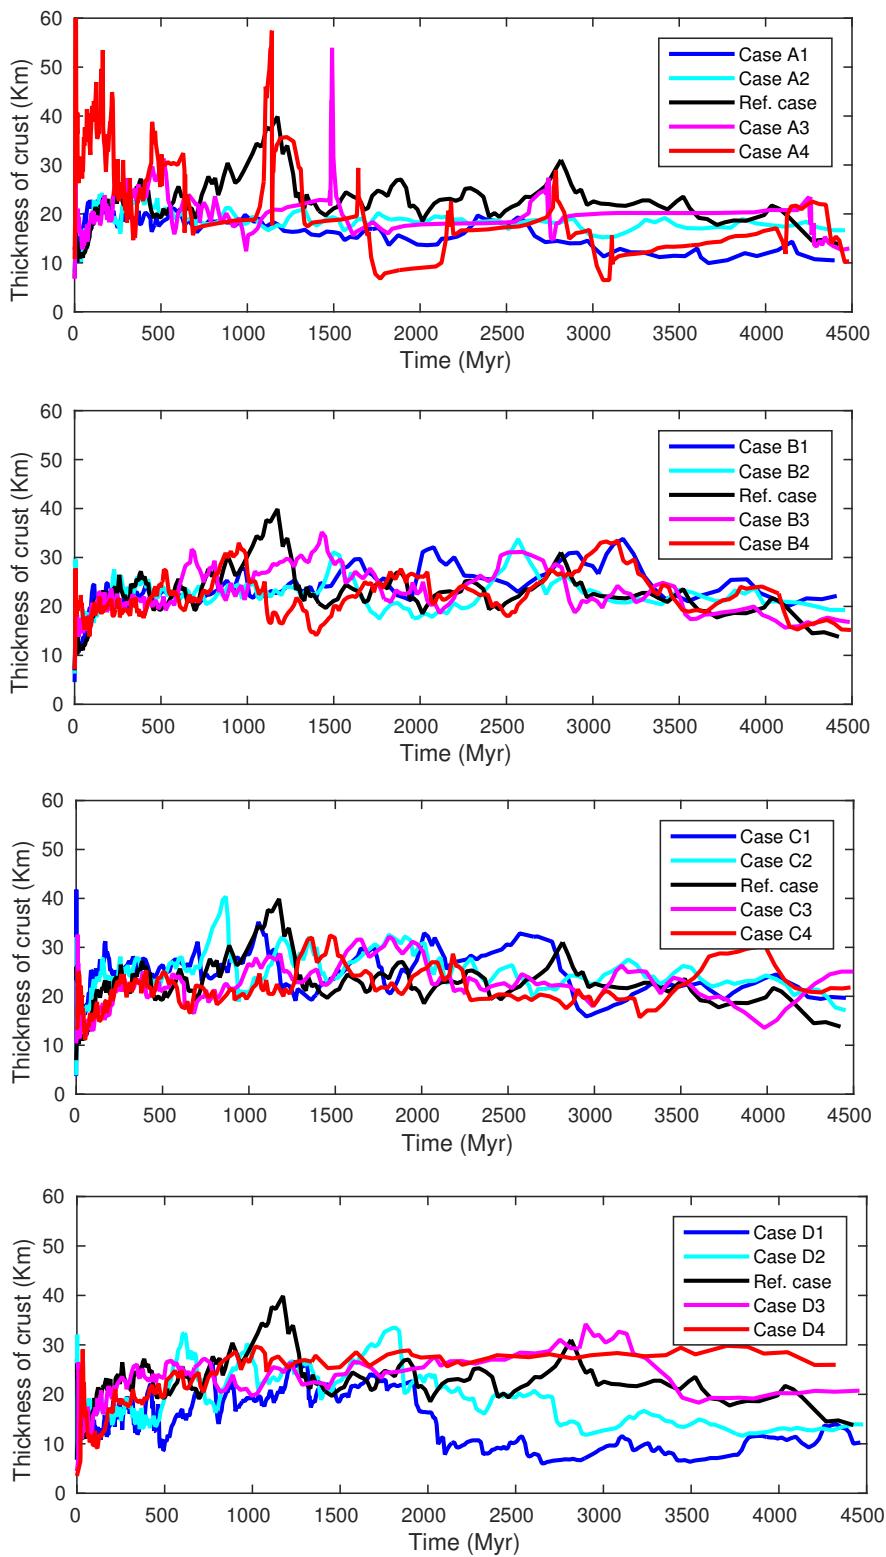

89 **Fig. S6.** Thermal evolution of the subset of models with variable viscosity profile. Left row:

90 core-mantle boundary (CMB) temperature; right row: CMB heat flux. Cases as labeled.

91

92 **Fig. S7.** Predicted crustal thickness along the surface at time 4.5 Gyr for a subset of cases
 93 modeled. Phi is the longitude of the spherical-annulus model. Note that crustal thickness for the
 94 reference case is < 15 km for much of the surface. Cases as labeled.

96 **Fig. S8.** Predicted crustal thickness (averaged along the surface) as a function of model time.
97 Crustal thicknesses are slightly higher than those on Earth. Note however that crustal thicknesses
98 in any given snapshot vary substantially (e.g. in regions of convergence) along the surface, and
99 are smaller than the average for most regions (Fig. S6). Cases as labeled.
