1. INTRODUCTION

In May 1987 surface sediment and periphyton samples were collected for diatom analysis from 27 upland lakes in mid- and north Wales (Figure 1). The sites were selected to provide a range of water acidities from circumneutral to strongly acid. The results, together with those collected from other regions in the British Isles, are to be used to produce a UK diatom-water quality data set that will facilitate calibration of sediment core diatom assemblages and reconstruction of past water quality characteristics such as pH (eg. Birks *et al.* 1990).

2. SAMPLING STRATEGIES

In most cases a Kajak corer was used to obtain surface sediment samples from at or near the deepest point in each lake. Normally, two independent surface sediment samples were collected, together with one sample of deeper sediment (ie. from approximately 15 cm below the sediment-water interface). Modern periphytic communities were sampled in each lake, usually from the epilithon and epiphyton. No attempt was made to collect diatom plankton directly since its seasonal occurrence often makes 'spot' sampling unrepresentative; surface sediments give a better indication of phytoplankton abundance. Water samples were collected from each lake for pH determination and further chemical analysis in the laboratory. Where possible notes about lake bathymetry and aquatic macrophytes were made.

Methods of sampling and laboratory analysis follow those described by Stevenson *et al.* (1987a).

3. SAMPLE SITES

Although water chemistry, lake biota and/or catchment geology and soils are probably the most useful criteria for classifying lakes, here sites are roughly grouped according to catchment vegetation and land-use and basin type. Six characteristic types were identified.

Group 1: lakes lie in obvious corries with much exposed rock, often with some blanket peat and supporting an acidophilous vegetation, usually *Calluna* and upland grasses. These sites are relatively high in altitude and deep, with maximum depths between 14 and 20 m and show a simple bathymetry with the deepest point lying near the back wall of the corrie.

Group 2: lakes similar in aspect to Group 1 sites but which do not occur within a typical corrie setting. They tend to be shallower and often have complex bathymetries; some are moraine dammed valley lakes others may owe their origins to differential erosion processes.

Group 3: lakes similar to those in Group 2, but the catchments have been afforested to varying degrees.

Group 4: lakes lie in catchments with blanket peats in areas of low relief; they are fairly shallow and contain brown water.

Group 5: lakes at lower altitude that have catchments with some improved pasture and/or some natural woodland, usually oak.

Group 6: lakes totally artificial in origin.

Table 1 Categorisation of sample lakes

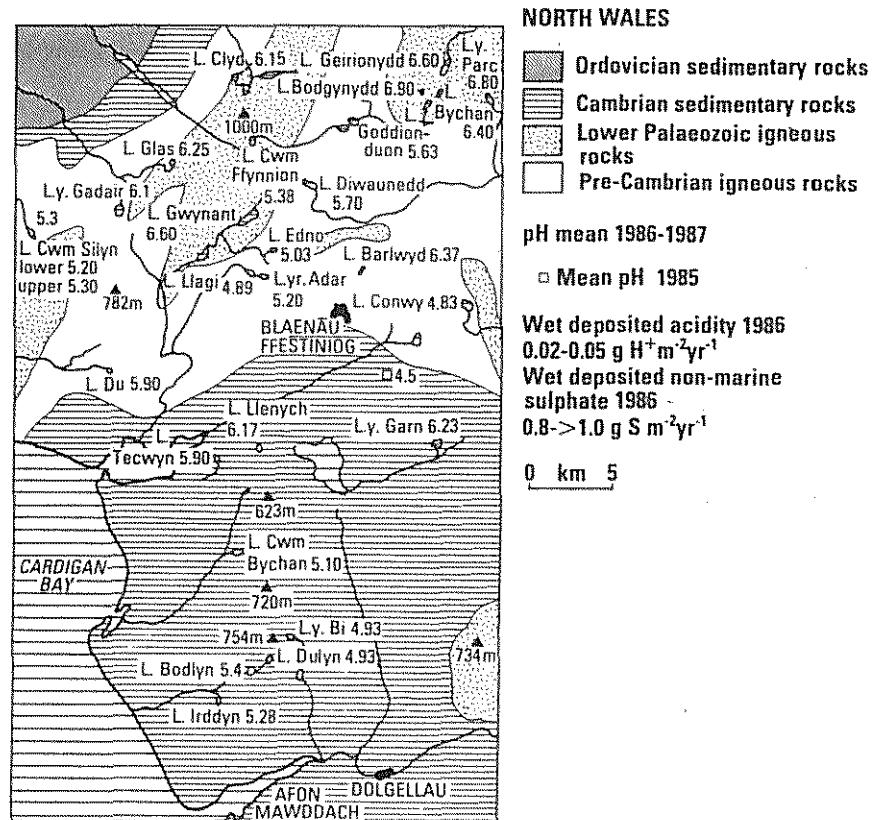

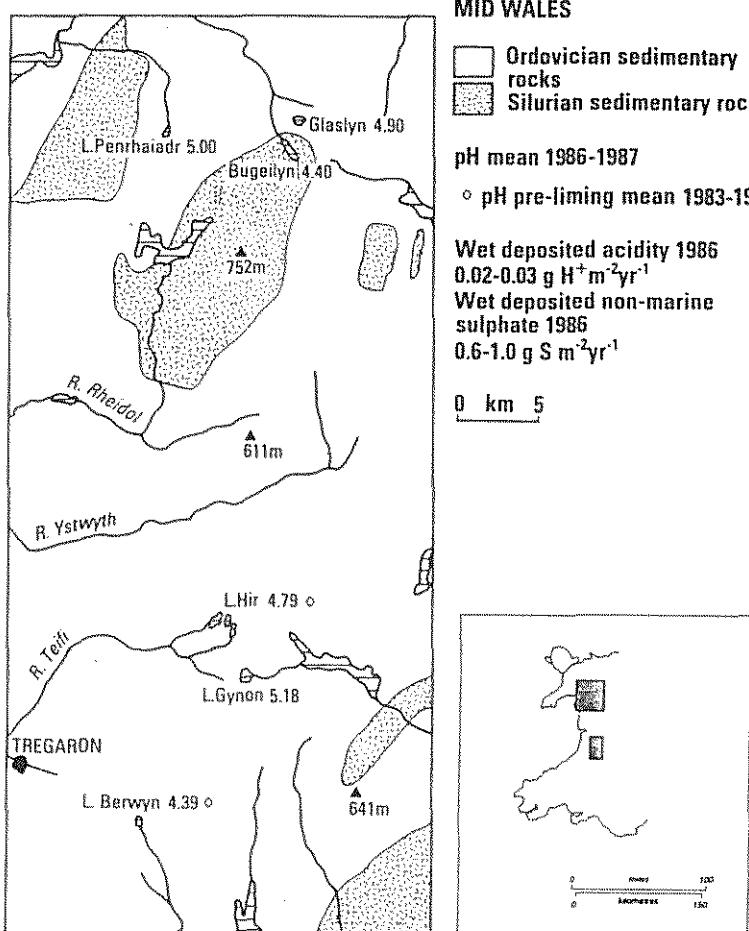

Lake	Group	Grid Ref.	Altitude (m)
L. Diwaunedd	1	SH 685536	375
L. Cwm Silyn	1	SH 512508	340
L. Bodlyn	1	SH 648238	450

L. y Gadair	5	SH 648564	380
L. Gwynant	5	SH 644529	70
L. Glasfryn	5	SH 403422	120
L. Barlwyd	6	SH 713486	558

Notes: some sites possess characteristics of several groups, for example a corrie setting at Llyn Bodlyn was unclear although its bathymetry indicates this origin; Llyn Llenyrch was surrounded by blanket peat but contained clear water. Only the Tecwyn, Gwynant and Cwm Bychan catchments possessed any remnants of natural oak forest. Several sites are also described by Jehu (1902), Ward (1931) and Liddle *et al.* (1979).

In order to extend the Welsh modern diatom-water quality data set further an additional five lakes have been added by using sites that have been previously the subject of detailed investigation by the Palaeoecology Research Unit. These comprise Llyn Berwyn (Kreiser *et al.* 1986) and Llyn Hir (Fritz *et al.* 1986) cored in 1984 and Llyn Llagi (Patrick *et al.* 1987), Llyn y Bi (Fritz *et al.* 1987), Llyn Gynon (Stevenson *et al.* 1987b) and Llyn Dulyn (Stevenson *et al.* 1987c) cored in 1985.

Figure 1 Location of sample sites

4

3.1 A systematic account of the sample sites.

Characteristics of each lake at the time of sampling (May 1987) are given below together with a summary of the diatoms and water chemistry. All data produced in this study are stored on the Palaeoecology Research Unit ORACLE data-base which was used to generate the full lists of surface sediment diatom taxa and of water chemistry for each site which are presented in Appendices 1 and 2 respectively.

Llyn Barlwyd (upper), sampled 13th May 1987, 14.30.

This artificial lake is situated (OS grid ref. SH 713486) 1.5 km north east of Blaenau Ffestiniog at 558⁴⁶⁰ m altitude and forms part of the water supply to the Llechwedd slate quarry. It is confined within a small catchment of grazed upland grasses by a 6 m high barrage. Blanket peats are exposed along the eastern margin of the lake and occasional tree remains are exposed where erosion is occurring.

The littoral area is soft and blocks of partially eroded submerged peat can be clearly seen. Aquatic macrophytes are common with *Callitricha*, *Sparganium*, *Littorella* and *Lobelia* all frequent. Small trout were also observed in the clear water. Most of the lake is c. 2 m deep with a maximum depth of almost 3 m near the centre. All the lake bed lies within the photic zone. Cores were taken from the deepest point and contained black organic sediment with chironomid tubes abundant at the mud/water interface.

pH	6.4	Cond.	35 $\mu\text{S cm}^{-1}$
Ca	130.7 $\mu\text{eq l}^{-1}$	DOC	1.9 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Bodgynydd, sampled 11th May 1987, 15.00

This lake is located at 300 m altitude in the Gwydyr Forest, near Betws-y-Coed (OS grid ref. SH 762593). The catchment is heavily afforested with conifers except in the northern sector where rough grazing for sheep occurs. Some clear-felling of the plantation is in progress at the southern end of the lake. In the south western sector birch, self-seeded pines, *Calluna*, *Erica* and *Vaccinium* are common. Inflows are very minor and at the outflow a 7 m barrage has been constructed indicating that formerly the lake was kept at a higher level for ore extraction purposes. Little evidence of mining activity was seen in the catchment although Ward (1931) states that the lake was fishless due to pollution from copper ore washings. Following restocking the lake now supports brown trout.

Epilithon was fairly abundant and aquatic macrophytes were plentiful and included *Potamogeton*, *Littorella*, and *Juncus bulbosus*. Maximum depth of the lake is 17 m and two sediment cores were collected from 16 m depth. The cores consisted of about 15 cm of black mud with lighter coloured material below, possibly indicating an erosion phase following afforestation or mining. The lake is also described by Liddle *et al.* (1979).

pH	6.9	Cond.	94 $\mu\text{S cm}^{-1}$
Ca	260.5 $\mu\text{eq l}^{-1}$	DOC	1.0 mg l^{-1}
Most common diatom: <i>Cyclotella kutziniana</i> v. <i>minor</i>			

Llyn Bodlyn, sampled 23rd May 1987, 17.30.

This lake (OS grid ref. SH 648238) lies 2 km north east of Llyn Irddyn at 450 m altitude. Its catchment is similar to that of Irddyn although slopes are much steeper and several almost vertical rock faces occur at the southern edge of the lake. According to Ward (1931) the lake contained trout of fine quality, perch and char; also at that time the lake was (and still is) used as a drinking water supply for Barmouth. During sampling no obvious signs of water level fluctuation were noticed although aquatic macrophytes were few and sampling was at a time when water level could be expected to be high. A sluice and associated barrage indicate that the lake level has been raised a metre or so sometime in the past. The deepest point in the lake is 20 m about 50 m off a cliff face on the south side of the lake. Two short cores of black homogeneous sediment (with no sign of inwash episodes) were collected from 19 m depth.

pH	5.4	Cond.	32 $\mu\text{S cm}^{-1}$
Ca	48.4 $\mu\text{eq l}^{-1}$	DOC	0.9 mg l^{-1}
Most common diatom: <i>Tabellaria flocculosa</i>			

Llyn Bugeilyn, sampled 17th May 1987, 12.00

This elongated lake in mid-Wales (OS grid ref. SN 822923) lies at 457 m altitude in a catchment composed of low hills where virtually all the land is given over to rough grazing for sheep. Blanket peats are extensive at either end of the lake and in flatter areas elsewhere. The lake is divided into two parts by a neck of land which carries the assess road. The lake possibly had a higher level in the past. Ward (1931) noted that the lake supported good trout fishing.

Aquatic macrophytes are few and dominated by several stands of *Nuphar*. The water is strongly coloured brown and secchi-disc depth was about 1.0 m. Most of the lake basin is about 2 m deep with a maximum depth of 2.25 m near the northern end. Two cores were collected at the deepest point although the very flocculant nature of the black organic sediment prevented the retrieval of cores with a completely undisturbed mud/water interface.

pH	5.1	Cond.	26 $\mu\text{S cm}^{-1}$
Ca	46.4 $\mu\text{eq l}^{-1}$	DOC	9.1 mg l^{-1}
Most common diatom: <i>Eunotia incisa</i>			

Llyn Bychan, sampled 15th May 1987, 11.30.

⁵¹³
This small lake (OS grid ref. SH 753794) lies at the edge of the Gwydyr Forest conifer plantations at 320 m altitude. The catchment is wholly afforested except for the steeply sloping north west sector. In the 1970s a forest fire in the catchment caused extensive erosion which has been well documented (Rumery 1983). Ward (1931) noted that the lake contained trout up to 2 lbs in weight.

Biologically the lake is relatively rich with extensive beds of aquatic macrophytes, including *Schonoplectus lacustris*, *Nuphar*, *Juncus bulbosus*, *Potamogeton*, *Phragmites*, and *Littorella*. Water is clear with a secchi-disc depth of c. 5 m. Unusually for the area, the lake appears to be free from heavy metal pollution and on the sampling day tadpoles were abundant. The lake is mostly <3 m deep but a deeper hole at c. 8 m occurs at the north eastern end of the lake. Two cores were obtained in 7 m of water and contained a 2-3 cm thick uppermost layer of oxidized fairly organic sediment above brown silty material, rich in inwashed material.

pH	6.6	Cond.	51 $\mu\text{S cm}^{-1}$
Ca	145.7 $\mu\text{eq l}^{-1}$	DOC	1.7 mg l^{-1}
Most common diatom: <i>Achnanthes minutissima</i>			

Llyn Clyd, sampled 24th May 1987, 14.00.

A small high altitude (660 m) lake which lies above the Nant Ffrancon valley below the summit of Y Garn (OS grid ref. SH 635597)

pH	6.1	Cond.	28 $\mu\text{S cm}^{-1}$
Ca	57.9 $\mu\text{eq l}^{-1}$	DOC	0.5 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Conwy, sampled 26th May 1987, 12.30.

A large lake (OS grid ref. SH 780463) which lies at 450 m altitude with a predominantly moorland catchment with much *Calluna* on blanket peat. Ward (1931) noted that the lake held great numbers of 0.25 lb trout. (See Patrick and Stevenson 1986 for a detailed description of the catchment and fishery history of this site).

Lake water is slightly brown coloured and the aquatic macrophytes, *Juncus bulbosus*, *Littorella* and *Sparganium* (especially around a small island in the southern corner of the lake) were observed; also few small trout were seen rising. Several cores from various depths were taken from the west side of the lake. A master core taken with a wide diameter piston corer in 7 m of water contained 1.72 m of homogenous dark brown organic sediment.

pH	4.8	Cond.	32 $\mu\text{S cm}^{-1}$
Ca	39.9 $\mu\text{eq l}^{-1}$	DOC	1.9 mg l^{-1}
Most common diatom: <i>Eunotia incisa</i> .			

Llyn Cwm Bychan: sampled 12th May 1987, 13.00.

A valley lake (OS grid ref. SH 640313) located at 191 m altitude near Harlech; the catchment is rugged with much outcropping rock in higher places; land-use is rough grazing for sheep but there remains some oak woodland on the southern slopes. Pockets of blanket peat have accumulated in low-lying areas near the south east end of the lake and some erosion is occurring. Some exploratory mining has taken place on the northern catchment slopes at sometime in the past. A farm exists near the main inflow at the east end of the lake. Ward (1931) noted that trout fishing was previously good but had declined due to over-fishing.

The eastern shore of the lake is fringed by *Juncus*. Epilithon was very sparse and aquatic macrophytes were represented by *Littorella* and apparently little else, although high water level hampered littoral sampling. Secchi-disc depth was c. 4 m, maximum depth was c. 14.5 m and two cores of dark grey sediment were collected from 13.5 m and 14.0 m respectively.

pH	5.2	Cond.	36 $\mu\text{S cm}^{-1}$
Ca	59.9 $\mu\text{eq l}^{-1}$	DOC	0.8 mg l^{-1}
Most common diatom: <i>Eunotia incisa</i>			

Llyn Cwm Ffynnion, sampled 14th May 1987, 18.30.

A very irregular shaped lake (OS grid ref. SH 648564), 1 km west of Pen y Gwryd, lying below the Glyders at 380 m altitude. The catchment is very steep and rocky to the north but the area around the lake is of low relief, covered with blanket peat and dominated by upland grasses which are grazed by sheep. The lake has moderately peaty water and Ward (1931) noted that it supported a few trout of very small size though fishing was apparently better before the level was lowered.

Aquatic macrophytes were few although the water was clear with a secchi-disc depth of about 6 m. Most of the lake is c. 3 m deep and organic sediments are uncommon. Most of the lake bed is composed of grey clay and bare rock. Repeated coring attempts showed that the clay possessed an upper crust of iron hydroxides and gravel and this occurred at the deepest point (11 m). Cores of organic sediment could only be obtained from shallower water (8 m depth) near the western shore. These cores consisted of black flocculant sediment ('liquefied peat').

pH	5.4	Cond.	22 $\mu\text{S cm}^{-1}$
Ca	40.4 $\mu\text{eq l}^{-1}$	DOC	1.1 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Cwm Silyn (lower), sampled 14th May 1987, 11.30.
Llyn Cwm Silyn (upper), sampled 14th May 1987, 13.30.

This exposed corrie lake, located 4 km east of Penygoes, is divided into two sections by a moraine, the upper lake (OS grid ref. SH 515505) and lower lake (OS grid ref. SH 512508) occur at about 340 m altitude with the latter higher by c. 2 m. There is much exposed rock in higher parts of the catchment and the back rock wall of the corrie slopes steeply into the upper lake at the south east end. In the west the catchment is of lower relief and is managed for sheep grazing. Land to the north and north east is less accessible and is dominated by *Calluna*. Soils are mainly minerogenic. Ward (1931) noted that the lake contained a small brown trout population.

In the Lower lake aquatic macrophytes were mainly submerged *Juncus bulbosus*, with *Lobelia* in the shallows. In the littoral green filamentous algae and diatoms occurred sparcely on stones in both sections of the lake. Maximum depth in the lower lake was 17 m although no useful core could be obtained at this point as late-glacial clay comprised the surface sediment. Successful cores were obtained at 11.5 m depth and contained c. 6 cm of brown flocculant oxidized sediment lying above brownish-grey sediment. Cores from the upper lake were obtained from the deepest point (18.5 m), some 30 m off the corrie back wall. They consisted of c. 6 cm of brown flocculant oxidized sediment lying above c. 6 cm of brownish-grey sediment, below which grey clay was present. The lake water was very clear with secchi-disc depths in the upper and lower lakes of 10 m and 7 m respectively.

Lower:	pH	5.2	Cond.	36 $\mu\text{S cm}^{-1}$
	Ca	35.4 $\mu\text{eq l}^{-1}$	DOC	undetectable
Most common diatom: <i>Achnanthes marginulata</i> v. <i>major</i>				
Upper:	pH	5.3	Cond.	33 $\mu\text{S cm}^{-1}$
	Ca	35.9 $\mu\text{eq l}^{-1}$	DOC	0.3 mg l ⁻¹
Most common diatom: <i>Achnanthes marginulata</i> v. <i>major</i>				

(nb. *Navicula tenuicephala* was also common at both sites)

Llyn Diwaunedd (upper), sampled 13th May 1987, 15.30.

This lake (OS grid ref. SH 685536), 3 km east of Snowdon, is divided by a line of boulders and till into upper and lower sections and has the appearance of a typical corrie lake. The natural barrier across the lake is probably a terminal moraine formed during the late-glacial readvance, a similar feature occurs in Llyn Cwm Silyn (see below). Exposed rock is common on higher ground and lower parts of the catchment are lightly grazed and *Molinia*, *Festuca*, and *Nardus* are common. Soils are predominantly minerogenic but blanket peat occurs locally. Extensive conifer plantations have been established around much of the lower lake. According to Ward (1931) the lake previously supported brown trout though fishing quality had declined by the 1930s.

Aquatic macrophytes were infrequent except for *Juncus bulbosus* which was abundant at the west end of the lake and adjacent to the dividing moraine. The lower lake at 13 m maximum depth is shallower than the upper where the maximum depth is 15.5 m. The deepest point in the latter lies about 50 m from the main inflow and when cored only about 3 cm of organic sediment was found overlying grey clay. Only one good core was collected at this site, in 14 m of water. The core contained c. 6 cm of brown oxidized, fairly organic sediment overlying a grey clay lens at 6-7 cm (inwash or redeposited glacial clay?) with greyish brown silty sediment with bryophytes below. Secchi-disc depth was c. 5.5 m.

pH	5.9	Cond.	26 $\mu\text{S cm}^{-1}$
Ca	47.9 $\mu\text{eq l}^{-1}$	DOC	0.7 mg l^{-1}
Most common diatom: <i>Brachysira brebissonii</i>			

Llyn Du, sampled 12th May 1987, 18.00.

This small lake (OS grid ref. SH 564425) lies a few kilometers north east of Portmadog in boggy ground below Mynydd Gorllwyn at an altitude of 255 m. The north west of the catchment contains a farm; here the land is of low relief and is given over to sheep grazing on raised quality pasture. The lake level has probably been lowered sometime in the past and some mining has occurred in the catchment. There are no clear inflows or outflows although a seepage outlet is probably through an alder/willow carr. Some drainage ditches have been cut through to the lake. Ward (1931) noted that small black trout were common in the lake.

The littoral is organic and fringed with aquatic macrophytes, *Carex rostrata*, *Littorella* and *Nuphar lutea* being common. Maximum depth is 7 m and two cores of black organic sediment were collected from 6.0 and 6.5 m depth. The water is brownish, secchi-disc depth being c. 1.5 m.

pH	6.2	Cond.	52 $\mu\text{S cm}^{-1}$
Ca	149.2 $\mu\text{eq l}^{-1}$	DOC	2.3 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Edno, sampled 24th May 1987, 16.00.

This lake (OS grid ref. SH 663497) lies at 550 m in a small catchment below Moel Meirch some 2 km south east of Llyn Gwynant. The catchment contains much exposed rock with extensive scree slopes adjoining the lake, especially along the north western shore. Blanket peat is common and *Nardus* grass supports low intensity sheep grazing immediately to the south west of the lake. Elsewhere *Calluna* and *Vaccinium* occur. The lake occurs at the junction of black shales and sandstones. In many respects the lake is physically similar to Llyn y Garn. Ward (1931) noted that the lake supported large trout.

Lake water is clear (secchi-disc depth c. 4.5 m) and fringing aquatic macrophytes, *Lobelia*, *Littorella*, and *Carex rostrata*, are common in sheltered bays. *Isoetes* occurs at depth. The lake has an unusual 'L' shape and has a complex bathymetry with at least three sub-basins, the deepest (20 m) occurs near the centre. Coring at this point showed that about 40 cm of black organic sediment overlies about 20 cm of gritty silt below which was grey clay; hence the area was unsuitable for coring with a Mackereth mini-corer. In the southern corner of the lake a 12 m deep sub-basin was located and yielded two c. 80 cm long cores of black organic sediment.

pH	5.0	Cond.	28 $\mu\text{S cm}^{-1}$
Ca	38.9 $\mu\text{eq l}^{-1}$	DOC	1.2 mg l^{-1}
Most common diatom. <i>Cyclotella kutzningiana</i>			

Llyn Geirionydd, sampled 11th May 1987, 18.00

This long narrow lake (OS grid ref. SH 765610) is also in the Gwydyr Forest area. It lies at 228 m altitude and the steep eastern slopes of its catchment are extensively planted with now mature conifers; rough grazing for sheep occurs on the western slopes. There has been considerable mining activity within the catchment (note the elevated zinc concentration - Appendix 2) and Ward (1931) states that the lake was devoid of fish at that time due to pollution from copper mining. The lake has now been stocked with trout which are apparently surviving.

Epilithon was sparse and aquatic macrophytes were few, only *Littorella* and mosses were observed. Maximum depth of the lake is 14.5 m and sediment cores were taken from 13.5 m and 14 m. The cores contained brown surficial sediment with leaf debris but became greyer below about 12 cm depth, probably reflecting soil inwash resulting from afforestation.

pH	6.6	Cond.	79 $\mu\text{S cm}^{-1}$
Ca	213.1 $\mu\text{eq l}^{-1}$	DOC	2.1 mg l^{-1}
Most common diatom: <i>Brachysira vitrea</i>			

Llyn Glas, sampled 24th May 1987, 12.30.

This small lake (OS grid ref. SH 601547) lies under the summit of Snowdon (on the west side) at 520 m altitude. The catchment is composed of boulder scree and where slopes are less steep, moorland grasses (including *Nardus*) occur on thin minerogenic soils; small pockets of blanket peat are also present. Other terrestrial plants include *Lycopodium* (two species) and *Rhacomitrium*. Ward (1931) recorded the presence of small trout in the lake and also noted that copper was mined in the immediate vicinity and suggested (wrongly) that the lake was artificial.

The lake water is very clear and the lake bottom is everywhere visible, however although common in shallow water, aquatic plants are limited to about 3 m depth. *Isoetes* is most abundant and forms a discrete fringe around the lake between 0.5 and 3.0 m depth. *Littorella* and the moss *Fontinalis* also occur and one small stand of *Potamogeton* was recorded. A few snails were observed on the surface sediment and reflect the relatively high pH of lake water which in turn reflects the local geology (pyroclastic rocks, including basic tuffs). The deepest point in the lake is 6.5 m towards the centre and several >1 m cores of grey sediment were collected. No blackening towards the top of any of these cores was observed.

pH	6.2	Cond.	26 $\mu\text{S cm}^{-1}$
Ca	65.9 $\mu\text{eq l}^{-1}$	DOC	<0.1 mg l^{-1}
Most common diatom: <i>Achnanthes detha</i>			

Llyn Glasfryn, sampled 18th May 1987, 12.00.

A shallow almost circular lake on the Lleyn Peninsular (OS grid ref. SH 403422) possessing several afforested small islands. This spring fed lake lies at low altitude (120 m) in countryside of moderate relief, the catchment is however very small and includes woodland and several pasture fields. The lake was drained in the 1930s to clear a population of coarse fish prior to the introduction of trout.

The water is clear and allows aquatic macrophytes to grow over the entire bed of the lake. Common aquatic macrophytes were *Menyanthes trifoliata*, *Nuphar* and *Carex rostrata*. Maximum depth is about 1 m and a sediment core recovered about 12 cm of brown silt overlying grey clay. The flora and fauna of the lake was described by Griffiths c. 1895 in a local natural history society journal.

pH	6.9	Cond.	31 $\mu\text{S cm}^{-1}$
Ca	390.7 $\mu\text{eq l}^{-1}$	DOC	5.7 mg l^{-1}
Most common diatom: <i>Fragilaria elliptica</i>			

Llyn Glaslyn, sampled 17th May 1987, 14.30.

This almost circular and relatively undisturbed lake (OS grid ref. SN 826941) lies at about 490 m altitude in a catchment partly given over to the sheep grazing; the western section is maintained as a *Calluna* heath. Ward (1931) noted that although several attempts at stocking the lake with trout had been made, the fish failed to survive.

The lake is very exposed and aquatic macrophytes appeared to be absent from the stone/gravel littoral area. Macrophytes possibly occur at depth since the water is very clear with a secchi-disc depth in excess of 7 m. The deepest point in the lake is 11 m, towards the centre. Coring showed the bottom to be grey clay at this point and this clay appeared to form the surface sediment below much of the lake. A patch of organic sediment was however located immediately to the west of the 11 m point at 9-10 m depth. The cores obtained consisted of about 12 cm of brown oxidised sediment (probably the mixed oxidized 'micro'zone) overlying grey clay.

pH	4.9	Cond.	30 $\mu\text{S cm}^{-1}$
Ca	34.9 $\mu\text{eq l}^{-1}$	DOC	0.8 mg l^{-1}
Most common diatom: <i>Achnanthes marginulata</i>			

Llyn Goddionduon, sampled May 15th 1987, 13.30

Llyn Goddionduon (OS grid ref. SH 754585) lies about 0.5 km south of Llyn Bychan at an altitude of 292 m. It has a completely afforested catchment, although selective felling of the forest is currently occurring. According to Ward (1931) the lake was even then destitute of fish.

Aquatic macrophyte beds are extensive along the western shore and similar in composition to those in Llyn Bychan. The lake is mostly shallow and the majority of the lake bed lies within the photic zone. Secchi-disc depth is about 6 m. The deepest point is at 7 m and occurs in a small depression near the western edge of the lake. Two cores were taken from 5.5 m water depth and contained organic sediment several centimeters thick overlying grey silty sediment. This latter sediment probably results from soil erosion following afforestation. The sediments of this lake have been extensively studied by researchers at Liverpool University.

pH	5.9	Cond.	52 $\mu\text{S cm}^{-1}$
Ca	102.3 $\mu\text{eq l}^{-1}$	DOC	1.4 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Gwynant, sampled 18th May 1987, 15.00.

A relatively large lake (OS grid ref. SH 644529) that lies at an altitude of only 70 m although the eastern slopes of the Snowdon massif and western slopes of Cerrig Cochion form much of the catchment. On flatter ground immediately to the north east of the lake, near the Afon Glaslyn inflow, sheep and cattle graze pasture of raised quality and in summer months the area is used as a camping ground. Some deciduous woodland, mainly oak and birch, as well as several farms occur in the catchment. Ward (1931) noted that the lake contained a good stock of trout and that the water level had been previously lowered.

Lake water was fairly clear with secchi-disc depth of 4.5 m, but aquatic macrophytes were few on the exposed eastern shore. *Juncus bulbosus* was locally common and *Myriophyllum* was abundant around the Glaslyn inflow. A maximum depth of 17 m occurs some 50 m off an escarpment on the north west shore and two cores were collected from 16.5 m depth. The top 12 cm of sediment was fairly silty and light brown in colour; a layer of grey silt/clay occurred below and possibly provides evidence of the nineteenth century lake level reduction or mining activity in the catchment.

pH	6.6	Cond.	37 $\mu\text{S cm}^{-1}$
Ca	117.8 $\mu\text{eq l}^{-1}$	DOC	0.8 mg l^{-1}
Most common diatom: <i>Achnanthes minutissima</i>			

Llyn Irddyn, sampled 23rd May 1987, 13.00.

An oval lake (OS grid ref. SH 630220) lying at 380 m at the foot of Craig y Grut (north east of Barmouth). The catchment is composed of sheep grazed upland grasses and exposed rock; blanket peat cover was not extensive. A substantial stone walled trackway and pens for sheep on the south side of the lake provide evidence of considerable shepherding activity in the past. Ward (1931) noted that the lake was well known for its excellent trout fishing, the lake apparently still supports fish today.

The water is clear, secchi-disc depth was c. 5 m and although littoral emergent macrophytes are rare (a few *Equisetum*) the lake bed is covered with a dense growth of *Isoetes lacustris*. A maximum depth of 8.75 m occurs towards the east shore although coring at this point showed the sediment to be composed of grey clay. Short cores of black organic sediment were obtained in 5.5 m of water c. 50 m south of the deepest point.

pH	5.1	Cond.	36 $\mu\text{S cm}^{-1}$
Ca	60.4 $\mu\text{eq l}^{-1}$	DOC	0.8 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn Llennych, sampled 12th May 1987, 15.30

The lake is located (OS grid ref. SH 655377) near Harlech at 255 m altitude and lies in a small catchment of low relief where sheep graze upland grasses and blanket peat predominates. Inflows are very minor. The littoral is composed of stones and blanket peat and exposed but submerged tree stumps (pine?) are present. It is described by Ward (1931) as a good trout lake.

Epilithon is fairly abundant as are the aquatic macrophytes, *Littorella*, *Lobelia* and *Equisetum*. Despite the apparent abundance of blanket peat the lake water is fairly clear with a secchi-disc depth of c. 4 m. Maximum depth was 10 m and cores of black sediment were collected from 9.5 m.

pH	6.2	Cond.	42 $\mu\text{S cm}^{-1}$
Ca	133.2 $\mu\text{eq l}^{-1}$	DOC	1.8 mg l^{-1}
Most common diatom: <i>Brachysira vitrea</i>			

Llyn Penrhaiadr, sampled 17th May 1987, 16.30.

This lake (OS grid ref. SN 753933) lies at 410 m in a peatland catchment where upland grasses predominate, afforestation is absent and some sheep grazing occurs. The lake has been sluiced but otherwise it is relatively undisturbed. According to Ward (1931) the lake contained good trout and perch.

The water is moderately peaty but secchi-disc depth was not determined. Littoral aquatic macrophytes consisted of *Juncus bulbosus*, *Carex rostrata* and *Littorella*. The deepest point of 7 m was located near the western shore and two cores of black organic sediment were collected from 6.5 m.

pH	5.2	Cond.	31 $\mu\text{S cm}^{-1}$
Ca	44.9 $\mu\text{eq l}^{-1}$	DOC	2.8 mg l^{-1}
Most common diatom: <i>Eunotia incisa</i>			

Llyn Tecwyn Isaf, sampled 18th May 1987, 18.00.

This relatively undisturbed and sheltered lake (OS grid ref. SH 629370) lies east of Harlech at 100 m altitude in a small catchment partially forested with oak woodland. The catchment also contains several fields with cattle grazing pasture. Ward (1931) noted that the lake supported trout and perch and that *Nuphar* was abundant, perch are still to be caught in the lake.

The current macrophytic vegetation of the lake consists of Nuphar, *Equisetum* and *Carex rostrata* with *Lythrum portula* common in the narrow littoral zone. Water is clear although slightly brown with a secchi-disc depth of c. 5 m. Most of the lake is 3-4 m in depth and the deepest point of 7 m occurs in the north eastern corner. Two cores were collected and both consisted of black homogeneous sediment.

pH	5.9	Cond.	60 $\mu\text{S cm}^{-1}$
Ca	152.7 $\mu\text{eq l}^{-1}$	DOC	1.4 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn y Gadair, sampled 14th May 1987, 15.00.

This lake (OS grid ref. SH 648564) lies in a glacial valley bottom at 380 m altitude and the western slopes of the catchment form part of the Snowdon massif. Improved quality pasture surrounds most of the lake and a raised trackway embankment has been constructed along the western shore. Conifers have been planted on the southern side and a disused quarry occupies the an area immediately to the west of the lake. Ward (1931) noted that the lake supported a good trout population.

Extensive beds of submerged *Juncus bulbosus* occur thoughout the lake and *Callitricha* was also abundant. The lake is everywhere shallow with a maximum depth of about 3 m and the entire lake bed lies within the photic zone. Cores consisted of black organic sediment.

pH	6.1	Cond.	35 $\mu\text{S cm}^{-1}$
Ca	93.3 $\mu\text{eq l}^{-1}$	DOC	1.8 mg l^{-1}
Most common diatom: <i>Fragilaria virescens</i> v. <i>exigua</i>			

Llyn y Garn, sampled 13th May 1987, 12.00.

This lake is situated (OS grid ref. SH 762377) north east of Trawsfynydd at an altitude of 510 m. The catchment is a rocky terrain and piles of frost shattered rock abound; large areas of rock debris are bare of vegetation. Bushy *Calluna* is the dominant vegetation type with occasional patches of *Molinia*. Land-management is minimal and consists of very irregular burning and light grazing by sheep, although little sign of sheep activity was seen. Oddly, Ward (1931) stated that the site held only perch at that time although it seems to resemble a typical upland trout lake.

In the littoral, epilithon was scarce and aquatic macrophytes were infrequent, only a few *Lobelia* were observed. Maximum depth was 19.5 m and cores of black sediment were collected from 18.5 m depth. The water was fairly clear, secchi-disc depth being 5.5 m.

pH	6.2	Cond.	38 $\mu\text{S cm}^{-1}$
Ca	110.8 $\mu\text{eq l}^{-1}$	DOC	1.1 mg l^{-1}
Most common diatom: <i>Cyclotella kutzningiana</i> v. <i>minor</i>			

Llyn y Parc, sampled 15th May 1987, 16.00.

The long narrow valley which contains this lake (OS grid ref. SH 793587) has been exploited in the past for mining purposes, zinc blende being the principal ore exploited (Dewey and Smith 1922). The lake lies at 246 m altitude and has had a sluice system installed at the southern end, although it is now inoperative. The lake is natural in origin although the water level was maintained several metres higher in the past (probably up until the 1930s), when the mine was worked. At the northern end there is a now redundant mine shaft and spoil heap. The lake catchment is wholly afforested with conifers except for a fringe of birch around the lake shore. There are at least two inflows to the lake and the one at the extreme north end is fed directly by mine drainage water.

Submerged aquatic macrophytes were mainly represented by large beds of *Juncus bulbosus* at the northern and southern ends of the lake. Additionally, a few small stands of *Potamogeton* were present at the southern extremity and at the northern end some *Phragmites* and *Carex rostrata* also occur. Aquatic invertebrates were few and a brief inspection revealed only corixids and midge larvae. Stones in the littoral were covered with fine silt and since catchment erosion appears to be minimal at present, this indicates that previously inwashed inorganic sediment (now forming the lake margins) is still being reworked within the lake during periods of wind induced water turbulence. Compared with other Gwydyr Forest lakes the secchi-disc depth of <4 m also indicated a higher loading of inorganic suspended material. The lake is divided into two main sub-basins of almost equal depth and at 11 m the north basin is the deepest by 0.5 m. A sediment core was collected from 10.5 m water depth in the northern basin. The core had a brown oxidized layer at the surface about 1 cm thick overlying a band of grey silt/clay also about 1 cm thick; the remaining c. 12 cm of mud was brownish grey and silty in nature. The inorganic appearance of the sediment strongly indicates that the lake has been impacted by inwash of mineral rich sediment, soil or mine waste. Although mining has now ceased it is possible that high rainfall could inwash old mine spoil to the lake.

The two factors affecting water quality in Llyn y Parc today are high silt loading and trace metal contamination (note high zinc values - Appendix 2) and both are a consequence of previous mining within the catchment. The lake was fishless before 1930 (Ward 1930) and apparently remains so today, almost certainly as a result of mining activity. Preliminary diatom analysis of the sediment core shows that although the lake possessed a substantial diatom phytoplankton in the past it is absent in the most recent sediment.

pH	6.8	Cond.	81 $\mu\text{S cm}^{-1}$
Ca	208.6 $\mu\text{eq l}^{-1}$	DOC	1.1 mg l^{-1}
Most common diatom: <i>Brachysira vitrea</i>			

3.2 Additional sites

Recent limnological and acidification histories of the following lakes are described in Palaeoecology Research Unit Research papers and are only briefly noted here.

Llyn y Bi; cored 1985 (Fritz *et al.* 1987)

1985-1987 mean:	pH	4.9	Cond. 43 $\mu\text{S cm}^{-1}$
	Ca	53.1 $\mu\text{eq l}^{-1}$	
Most common diatom: <i>Tabellaria binalis</i>			

Llyn Llagi; cored 1985 (Patrick *et al.* 1987)

1985-1987 mean:	pH	4.9	Cond. 31 $\mu\text{S cm}^{-1}$
	Ca	60.5 $\mu\text{eq l}^{-1}$	
Most common diatom: <i>Tabellaria quadriserrata</i>			

Llyn Gynon; cored 1985 (Stevenson *et al.* 1987b)

1984-1987 mean:	pH	5.2	Cond. 34 $\mu\text{S cm}^{-1}$
	Ca	41.4 $\mu\text{eq l}^{-1}$	
Most common diatom: <i>Fragilaria virescens v.exigua</i>			

Llyn Dulyn; cored 1985 (Stevenson *et al.* 1987c)

pH 4.9 Cond. 36.2 $\mu\text{S cm}^{-1}$
Ca 49.4 $\mu\text{eq l}^{-1}$
Most common diatom: *Aulacoseira* [sp. 4] Loch Moan
(R.J.F) 1988 (= *A. lyrata* v. *alpeginata* Haworth)

Llyn Berwyn; cored 1984 (Kreiser *et al.* 1986)

1984-1987 mean:
(pre-liming) pH 4.4 Cond. 58 $\mu\text{S cm}^{-1}$
 Ca 41.2 $\mu\text{eq l}^{-1}$
 Most common diatom: *Eunotia incisa*

Llyn Hir; cored 1984 (Fritz *et al.* 1986)

1984-1987 mean:
(pre-liming) pH 4.8 Cond. 44 $\mu\text{S cm}^{-1}$
 Ca 46.3 $\mu\text{eq l}^{-1}$
 Most common diatom: *Eunotia incisa*

4 General observations and conclusions

- 1) The spatial distribution of sediment was strongly asymmetric in several lake basins (Glaslyn, upper and lower Cwm Silyn, Ireddyn and Diwaunedd). A combination of basin morphometry and wind induced water movements may be responsible for depositing detrital sediments in shallower areas.
- 2) Palaeolimnological studies have shown that Llyn Gynon, Llyn y Bi, Llyn Dulyn, Llyn Berwyn and Llyn Hir are all recently acidified. From a brief consideration of the diatoms and water chemistry, several lakes in this study set have almost certainly acidified in recent years (eg. Glaslyn - pH <5, clear water).
- 3) Llyn y Garn is probably the best example of an upland acid lake which still possesses a rich *Cyclotella* flora. This site has catchment vegetation consisting predominantly of *Calluna* and in recent decades active land-management appears to have been minimal. This site would make a good comparison with sites with managed grassland catchments (eg. in the Rhinnogs).

4) Some of these Welsh lakes (eg. Llyn Berwyn and Llyn Hir - pre-liming) appear to have a less acidobiontic diatom flora than some Galloway lakes of comparable pH. This suggests that other factors in addition to pH may be important here.

5) Lakes in the Gwydyr Forest and Llyn Gwynant have been severely impacted by mining activity in the past. Diatom analysis of cores from these sites could provide important information on the ecological effects of this form of pollution and help in establishing restoration plans. Zinc pollution could account for the very high frequencies of *Brachysira vitrea* in Llyn y Parc and Llyn Geirionydd.

6) The surface sediment diatoms of these Welsh lakes show a strong correspondence with lake water pH and following numerical analysis (Birks *et al.* 1990) should provide a useful calibrational data sub-set.

Appendix 2.

Water chemistry data for the 33 lakes. The data are those used in the SWAP diatom-pH calibration procedures (Birks *et al.* 1990). Note that for the two limed lakes (Llyn Hir and Llyn Berwyn) only mean pH values prior to liming are given.

Palaeoecology Research Unit: Research papers

- No. 1 **Patrick, S.T. & Battarbee, R.W.** 1981
The influence of sanitary and other social changes on the eutrophication of Lough Erne since 1850: project introduction and a consideration of the potential role of metabolic wastes.
- No. 2 **Battarbee, R.W.** 1983
Diatom analysis of River Thames foreshore deposits exposed during the excavation of a Roman waterfront site at Pudding Lane, London.
- No. 3 **Patrick, S.T. & Battarbee, R.W.** 1983
Rural sanitation in the Lough Erne catchment: history and influence on phosphorus loadings.
- No. 4 **Patrick, S.T.** 1983
The calculation of per capita phosphorus outputs from detergents in the Lough Erne catchments.
- No. 5 **Patrick, S.T.** 1983
Phosphorus loss at sewage works in the Lough Erne region.
- No. 6 **Flower, R.J. & Battarbee, R.W.** 1983
Acid lakes in the Galloway uplands, south west Scotland: catchments, water quality and sediment characteristics.
- No. 7 **Patrick, S.T.** 1984
The influence of industry on phosphorus loadings in the Lough Erne region.
- No. 8 **Battarbee, R.W. & Flower, R.J.** 1985
Palaeoecological evidence for the timing and causes of lake acidification in Galloway, south west Scotland.
- No. 9 **Raven, P.J.** 1985
The use of aquatic macrophytes to assess water quality changes in some Galloway Lochs: an exploratory study.
- No. 10 **Anderson, N.J. & Battarbee, R.W.** 1985
Loch Fleet: bathymetry and sediment distribution.
- No. 11 **Battarbee, R.W.** 1985
Diatoms and acid lakes: proceedings of a workshop.
- No. 12 **Battarbee, R.W. & Renberg, I.** 1985
Royal Society Surface Water Acidification Project (SWAP) palaeolimnology programme.

- No. 13 **Raven, P.J.** 1986
Occurrence of *Sphagnum* moss in the sublittoral of several Galloway lochs, with particular reference to Loch Fleet.
- No. 14 **Flower, R.J., Rippey, B. & Tervet, D.** 1986
34 Galloway lakes: bathymetries, water quality and diatoms.
- No. 15 **Flower, R.J. & Nicholson, A.** 1986
Bathymetries, water quality and diatoms of lochs on the island of South Uist, the Outer Hebrides, Scotland.
- No. 16 **Fritz, S.C., Stevenson, A.C., Patrick, S.T., Appleby, P.G., Oldfield, F., Rippey, B., Darley, J. & Battarbee, R.W.** 1986
Palaeoecological evaluation of the recent acidification of Welsh lakes. I, Llyn Hir, Dyfed.
- No. 17 **Anderson, N.J., Battarbee, R.W., Appleby, P.G., Stevenson, A.C., Oldfield, F., Darley, J. & Glover, G.** 1986
Palaeolimnological evidence for the recent acidification of Loch Fleet, Galloway.
- No. 18 **Kreiser, A., Stevenson, A.C., Patrick, S.T., Appleby, P.G., Rippey, B., Darley, J. & Battarbee, R.W.** 1986
Palaeoecological evaluation of the recent acidification of Welsh lakes. II, Llyn Berwyn, Dyfed.
- No. 19 **Patrick, S.T. & Stevenson, A.C.** 1986
Palaeoecological evaluation of the recent acidification of Welsh lakes. III, Llyn Conwy and Llyn Gamallt, Gwynedd (site descriptions, fishing and land use/management histories).
- No. 20 **Stevenson, A.C., Patrick, S.T., Fritz, S.C., Rippey, B., Oldfield, F., Darley, J., Higgitt, S.R., & Battarbee.** 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. IV, Llyn Gynon, Dyfed.
- No. 21 **Patrick, S.T.** 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. V, The significance of land use and land management.

- No. 22 Stevenson, A.C., Patrick, S.T., Fritz, S.C., Rippey, B., Appleby, P.G., Oldfield, F., Darley, J., Higgitt, S.R., Battarbee, R.W. & Raven, P.J. 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. VI, Llyn Dulyn, Gwynedd.
- No. 23 Fritz, S.C., Stevenson, A.C., Patrick, S.T., Appleby, P.G., Oldfield, F., Rippey, B., Darley, J., Battarbee, R.W., Higgitt, S.R. & Raven, P.J. 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. VII, Llyn y Bi, Gwynedd.
- No. 24 Patrick, S.T., Fritz, S.C., Stevenson, A.C., Appleby, P.G., Rippey, B., Oldfield, F., Darley, J., Battarbee, R.W., Higgitt, S.R. & Raven P.J. 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. VIII, Llyn Eiddew Bach, Gwynedd.
- No. 25 Patrick, S.T., Stevenson, A.C., Fritz, S.C., Appleby, P.G., Rippey, B., Oldfield, F., Darley, J., Battarbee, R.W., Higgitt, S.R. & Raven P.J. 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. IX, Llyn Llagi, Gwynedd.
- No. 26 Stevenson, A.C., Patrick, S.T., Kreiser, A. & Battarbee, R.W. 1987
Palaeoecological evaluation of the recent acidification of susceptible lakes: methods utilised under DoE contract PECD 7/7/139 and the Royal Society SWAP project.
- No. 27 Kreiser, A., Patrick, S.T., Stevenson, A.C., Appleby, P.G., Rippey, B., Oldfield, F., Darley, J., Battarbee, R.W., Higgitt, S.R. & Raven P.J. 1987
Palaeoecological evaluation of the recent acidification of Welsh lakes. X, Llyn Cwm Mynach, Gwynedd.
- No. 28 Jones, V.J., Stevenson, A.C. & Battarbee, R.W. 1987
A palaeolimnological evaluation of peatland erosion. Report (First phase) to the NCC.
- No. 29 Flower, R.J., Patrick, S.T., Appleby, P.G., Oldfield, F., Rippey, B., Stevenson, A.C., Darley, J. & Battarbee, R.W. 1988
Palaeoecological evaluation of the recent acidification of Loch Laidon, Rannoch Moor Scotland.

- No. 30 Anderson, N.J., Patrick, S.T., Appleby, P.G., Oldfield, F., Rippey, B., Richardson, N., Darley, J. & Battarbee, R.W. 1988
An assessment of the use of reservoir sediments in the southern Pennines for reconstructing the history and effects of atmospheric pollution.
- No. 31 Patrick, S.T., Flower, R.J., Appleby, P.G., Rippey, B., Stevenson, A.C., Cameron, N., Darley, J. and Battarbee, R.W. 1988
Palaeoecological evaluation of water quality change in Loch Urr, Galloway, Scotland.
- No. 32 Flower, R.J., Patrick, S.T., Appleby, P.G., Oldfield, F., Rippey, B., Stevenson, A.C., Darley, J. and Battarbee, R.W. 1988
Palaeoecological evaluation of the recent acidification of Loch Tanna, Arran, Scotland.
- No. 33 Rose, N.L. 1989
A method for the extraction of carbonaceous particles from lake sediment.
- No. 34 Patrick, S.T., Flower, R.J., Appleby, P.G., Oldfield, F., Rippey, B., Stevenson, A.C., Darley, J., Raven, P.J. & Battarbee, R.W. 1989
Palaeoecological evaluation of the recent acidification of Lochnagar, Scotland.
- No. 35 Rose, N.L. 1989
An extraction technique for mineral ash particles in lake sediment.
- No. 36 Battarbee, R.W. 1989
The acidification of Scottish lochs and the derivation of critical sulphur loads from palaeolimnological data
