4 1 ABSTRACT  
5  
6

7 2 Childhood malnutrition is highly prevalent and associated with high mortality  
8 3 risk. In observational and interventional studies among malnourished children  
9 4 body composition is increasingly recognised as a key outcome. The deuterium  
10 5 dilution technique has generated high-quality data on body composition in studies  
11 6 of infants and young children in several settings, but its feasibility and accuracy  
12 7 in children suffering from moderate acute malnutrition requires further study.

13 8 Prior to a large nutritional intervention trial among children with moderate acute  
14 9 malnutrition we conducted pilot work to develop and adapt the deuterium  
15 10 dilution technique. We refined procedures for administration of **isotope** doses and  
16 11 collection of saliva. Furthermore, we established that equilibration time in local  
17 12 context is 3 hours.

18 13 These findings and the resulting standard operating procedures are **important to**  
19 14 **improve data quality when using the deuterium dilution technique in malnutrition**  
20 15 **studies in field conditions**, and may encourage a wider use of isotopes techniques.

## 1. Introduction

Childhood malnutrition continues to be highly prevalent and is associated with high mortality risk [1]. Traditionally, outcomes in studies addressing malnutrition have been based on anthropometry i.e. weight, weight-for-height z-score (WHZ) or mid-upper-arm circumference (MUAC). These outcomes, however, do not discriminate between fat and lean mass. Lean mass is likely to mediate many of the beneficial functional outcomes, whereas fat is important as an energy substrate, and may play a role promoting immune function, but may also increase the long term risk of chronic diseases [2].

As yet, it is unclear how lean and fat mass might benefit survival in early life. Low levels of leptin, associated with fat mass, predict mortality in children with severe acute malnutrition (SAM) [3], but lean mass has also been proposed to promote survival [4,5]. Highly precise methods for the assessment of body composition such as air-displacement plethysmography or dual-energy X-ray absorptiometry are used in research settings, but are impractical and expensive to use in larger field studies [6,7].

The deuterium dilution technique offers a logistically more feasible alternative in field studies by obtaining measurements of total body water (TBW) from which the two components of fat and lean mass can be derived. The use of the deuterium dilution technique has generated high-quality data on body composition in studies of infants and young children in several low- and middle-income country settings (Peru [8], Gambia [9], Ethiopia [10], Nepal [11], India [12]), and in larger trials of moderate acute malnutrition (MAM) prevention in countries such as Cambodia and Kenya [13].

We chose absolute lean mass increment measured using the deuterium dilution technique as the primary outcome in a large randomized trial (Treatfood) conducted in Burkina Faso among children aged 6-23 months and suffering from MAM (weight-for-

1  
2  
3 45 height z score (WHZ) between  $-3$  and  $-2$ , and/or a measure of mid-upper arm  
4  
5 46 circumference (MUAC) between 115 and 124 mm) [14].  
6

7 In principle, measurement of TBW by isotopic methods is relatively simple in  
8  
9 48 most age groups, requiring only the collection of urine or saliva samples, before and  
10  
11 49 after a single dose of deuterium labelled water. In practice, several **methodological**  
12  
13 50 issues need to be addressed, particularly in younger age groups. We have previously  
14  
15 51 evaluated different methods of administering isotope doses to healthy breastfed babies  
16  
17 52 in a high-income setting, who may be unfamiliar with drinking water [15], but a wider  
18  
19 53 range of **methodological** issues may be challenging when applying the method to  
20  
21 54 children with MAM **studied under difficult field conditions, such as in rural Africa.**  
22  
23  
24

25 In addition, low costs relative to isotope-ratio mass-spectrometry make Fourier  
26  
27 56 transform infrared spectroscopy (FTIR) an attractive analytical option for large trials.  
28  
29 57 However, FTIR requires saliva samples, but many previous isotope studies in infants  
30  
31 58 and young children used urine samples, and little is known of the feasibility of saliva  
32  
33 59 sampling in younger age groups, especially in challenging field conditions, such as hot  
34  
35 60 and arid environments.  
36  
37

38 Prior to our trial, we therefore conducted pilot work to adapt and develop the  
39  
40 62 deuterium dilution technique specifically for use in children with MAM and the local  
41  
42 63 Burkinabe setting, while also testing large-scale logistical feasibility. This paper  
43  
44 64 describes our efforts to (a) optimise the processes of saliva sampling and fluid  
45  
46 65 administration, (b) evaluate the effects on the analysis technique of adding of sugar to  
47  
48 66 the **isotope dose** to promote palatability, (c) minimise fractionation bias in collecting  
49  
50 67 saliva, (d) minimise evaporation through **isotope dose** spillage, (e) evaluate **precision of**  
51  
52 68 **isotope abundance** determination **in aliquots taken at intervals from a single** deuterium  
53  
54  
55

58  
59  
60

69 **oxide** stock solution and (f) to determine **isotope** equilibration time in children with  
70 MAM.

## 71 **2. Methods**

72 The pilot study took place in Province du Passoré at Gonpomsom Health centre  
73 in the Northern region of Burkina Faso in January–February 2013. Characteristics of  
74 methods, participants and samples are described in the relevant sub-studies (a-f) below.

### 75 *2.1 Basic protocol and analytical technique*

76 From application of the deuterium dilution technique an estimation of TBW is  
77 obtained from which the two components of fat mass (FM) and fat free mass (FFM) can  
78 be derived. Calculation of TBW requires information on baseline level of isotopic  
79 **abundance** in the body water pool, the isotopic **abundance** of the dose solution, and  
80 post-dose levels of isotopic **abundance** in the body water pool.

81 The basic protocol for **body composition assessment** therefore consists of four  
82 different procedures. (1) Collection of a pre-dose saliva sample to establish the baseline  
83 level of deuterium **oxide** ( $^2\text{H}_2\text{O}$ ) in child. (2) Administration of a dose consisting of  
84  $^2\text{H}_2\text{O}$  (99.8 %, Cambridge Isotope Laboratories Inc., Andover, USA), diluted with  
85 **water**, followed by an appropriate equilibration period. (3) Collection of a post-dose  
86 saliva sample. (4) Determination of isotope **abundances** in these samples by Fourier  
87 Transform Infrared Spectrometer (FTIR) (IRAffinity-1, Shimadzu, Kyoto, Japan) at St.  
88 John's Research Institute (Bangalore, India). This approach quantifies the relative  
89 concentrations of  $^1\text{H}_2\text{O}$  versus  $^2\text{H}_2\text{O}$  in fluid samples.

91 To calculate the deuterium dilution space (N) the following equation is used [16]:

1  
2  
3 93  $N = (T \cdot A / a) \cdot [(E_d - E_t) / (E_s - E_p)]$   
4  
5  
6

7 94

8 95 Where:

9 96 *T is the diluent (mass of tap water for dilution in lab + mass of dose diluted in lab) (g)*

10 97 *A is the mass of the dose ingested by child in field (g)*

11 98 *a is the mass of the dose that is further diluted in lab for FTIR analysis (g)*

12 99 *Ed is the isotopic abundance of the dose solution (ppm)*

13 100 *Et is the isotopic abundance of the tap water used to dilute the dose in lab (ppm)*

14 101 *Es is the isotopic abundance of the post-dose sample of saliva (ppm)*

15 102 *Ep is the isotopic abundance of the pre-dose sample of saliva (ppm)*

16 103

17 104 Subsequently the two-component body composition can be derived as:

18 105

19 106  $TBW (g) = N / 1.044$  (adjusted for exchange of hydrogen atoms in tissues [17,18])

20 107  $FFM (g) = TBW / \text{hydration factor}$  [19,20]

21 108  $FM (g) = \text{Body weight} - FFM$

22 109

23 110 In our study, the aim was not to calculate body composition using this method, but

24 111 rather to optimise several discrete components of the protocol, by resolving challenges

25 112 expected in children with moderate acute malnutrition. These specific issues are

26 113 described below.

2  
3 114 **2.2 Pilot studies**  
4

5  
6 115 *Sub-study (a): feasibility of saliva sampling and fluid administration*  
7

8 116 The first issue concerns questions of feasibility for the field part of the basic  
9  
10 117 protocol in children with MAM: how should the saliva samples be collected to obtain  
11  
12 118 adequate volumes, and how should the dose be administered to get an accurately  
13  
14 119 quantified measurement of dose ingested by infant. This first sub-study involved 23  
15  
16 120 children 6-30 months old, consisting of well-nourished children (n=12); MAM (n=8);  
17  
18 121 and severe acute malnutrition (SAM) (n=3).  
19  
20  
21  
22

23  
24  
25 123 **Saliva sampling**  
26

27 124 Our success criterion for saliva collection was a target volume of a minimum of  
28  
29 125 0.5 ml. In preliminary work, we tested viability of passive collection by a “cotton ball  
30  
31 126 method” as recently applied in field setting, which involves putting a cotton wool ball  
32  
33 127 with a string attached in the mouth of the child and wait until it is wet with saliva [13].  
34  
35 128 Subsequently active collection by lavage of the oral cavity with a “cotton stick method”  
36  
37 129 was developed by applying extra layers of cotton to regular cotton sticks. Possible  
38  
39 130 fractionation bias in saliva collection was tested in sub-study (c).  
40  
41  
42

43 131

44  
45 132 *Fluid administration*  
46

47 133 Our success criterion for fluid (dose) administration was finding an approach  
48  
49 134 that led to high acceptability whilst enabling precise measurements of the volume  
50  
51 135 ingested. For ethical considerations, neither nasogastric tubes nor administration by  
52  
53 136 intravenous route was considered. Oral fluid administration using water was tested  
54  
55 137 using (1) disposable syringes, (2) syringes with a short butterfly catheter placed in  
56  
57  
58  
59  
60

1  
2  
3 138 mouth, (3) various local cups and (4) different types of baby bottles with teat holes in  
4  
5 139 various sizes. We also evaluated whether the addition (dilution) to the dose with a well-  
6  
7 140 known local drink, Bissap (sugary and containing hibiscus), would improve palatability  
8  
9 141 (sub-study (b)). The effect of local climatic conditions on evaporation of spillage was  
10  
11 142 tested separately in sub-study (d).  
12

13  
14  
15 143 *Sub-study (b): the effects of adding of sugar to the **dose solution***  
16

17  
18 144 Our success criterion when evaluating the addition of Bissap to the dose solution  
19  
20 145 was that analytic accuracy was maintained in the FTIR analysis. Bissap contains sugar  
21  
22 146 and to our knowledge no data is available on the effect of sugar on accuracy of **the  $^2\text{H}_2\text{O}$**   
23  
24 147 **abundance determination** by FTIR. Diluted  $^2\text{H}_2\text{O}$  (0.1g/ml) with and without sugar  
25  
26 148 (sucrose at about 2 teaspoons of sugar in 100 ml) was analysed by FTIR, to identify the  
27  
28 149 possible interference of sugar.  
29  
30  
31

32  
33 150 *Sub-study (c): fractionation bias in collecting saliva*  
34

35  
36 151 This sub-study was undertaken in seven adult volunteers. The objective was to  
37  
38 152 evaluate the effect on isotopic **abundance** of saliva sampled with an open mouth versus  
39  
40 153 a closed mouth. It is unknown whether collecting saliva from an open mouth might  
41  
42 154 cause isotopic fractionation, whereby heavy and light isotopes evaporate at different  
43  
44 155 rates. This would alter the relative isotopic **abundance** of the sample and yield  
45  
46 156 inaccurate data on body composition.  
47

48  
49 157 Ambient temperature was  $\sim 38^\circ\text{C}$  [21] during the experiments. Undiluted  $^2\text{H}_2\text{O}$ ,  
50  
51 158 administered in proportion to body weight was ingested (0.4 g  $^2\text{H}_2\text{O}$  per kg body  
52  
53 159 weight). In the four-hour waiting period individuals minimised physical activity. No  
54  
55 160 drinking or eating 30 min. before saliva sampling was permitted, nor rinsing of the  
56  
57 161 mouth at any time. Saliva was collected using the cotton stick method while the  
58  
59  
60

1  
2  
3 162 participant's mouth was kept closed. After 3 minutes, saliva collection was repeated  
4  
5 163 with an open mouth while the required volume of saliva was collected. The aim was to  
6  
7 164 obtain 1 ml of saliva. If more than 0.5 ml saliva was obtained after the use of four  
8  
9 165 cotton sticks the experiment was terminated. If <0.5 ml saliva additional cotton-stick  
10  
11 166 sampling would be performed.  
12  
13  
14  
15  
16  
17

18 *Sub-study (d): evaporation through dose spillage*

19  
20 169 When administering  $^2\text{H}_2\text{O}$  to a child, small amounts of the dose may not be  
21  
22 170 consumed, and may be spilled. If these spills are not recovered, the volume of dose  
23  
24 171 administered would be over-estimated, leading eventually to an over-estimation of  
25  
26 172 TBW by the same percentage magnitude. It is therefore necessary to collect spillages,  
27  
28 173 for example on pre-weighed pieces of gauze (tissue), so that the mass of spillage can be  
29  
30 174 quantified. In a hot, dry setting, however, these spillages may rapidly evaporate.  
31  
32  
33 175 Evaporation was tested in four small experiments with 3 pieces of gauze tested in each.  
34  
35 176 Gauzes were prepared with ~1 g diluted  $^2\text{H}_2\text{O}$ , placed in sealed plastic bags and  
36  
37 177 weighed with 0.01 g precision (Adam equipment: model CQT 202, United Kingdom).  
38  
39 178 On opening the bags, half the pieces of gauze were curled up and pressed against the  
40  
41 179 lower lip of an adult study participant to mimic "normal collection" of spillage on the  
42  
43 180 face for three or seven minutes. The other half was left to "free-dry" in the air for three  
44  
45  
46 181 to seven minutes. After exposure, each piece of gauze was transferred back to its bag  
47  
48 182 and reweighed.  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 183 *Sub-study (e): precision of dosing isotope abundance determination from stock*  
4  
5 184 *solution*

6  
7 185 Calculation of TBW requires precise knowledge of both the mass of the dose  
8  
9 186 and the *abundance* of isotope in the dose. A Diluted Deuterium oxide Stock (DDS) is  
10  
11 187 prepared by mixing commercially available  $^2\text{H}_2\text{O}$  and water. As successive doses are  
12  
13 188 removed from the stock solution, its isotopic content may change, such that the doses do  
14  
15 189 not share a common isotopic abundance. The objective of this study was to test if  
16  
17 190 isotope *abundance of DDS samples* would be similar when measured repeatedly on  
18  
19 191 different days. We determined the isotopic *abundance* of several DDS samples (in each  
20  
21 192 case sampled from the mid-bottle of a DDS solution) taken from two different DDS  
22  
23 193 solutions (both ~40% solution ~400 g  $^2\text{H}_2\text{O}$  and ~600 g  $\text{H}_2\text{O}$ ). The first DDS solution  
24  
25 194 was sampled on days 1,2,5,6 and 7. The second DDS solution was sampled on days 1, 2  
26  
27 195 and 5.  
28  
29  
30  
31

32 196  
33  
34  
35 197 *Sub-study (f): Equilibration time*

36  
37  
38 198 The objective of this sub-study was to establish the  $^2\text{H}_2\text{O}$  equilibration time in  
39  
40 199 saliva for children with MAM. The experimental overview is seen in **figure 1**.  
41  
42 200 Following collection of baseline saliva, 10 ml of diluted  $^2\text{H}_2\text{O}$  (~40% concentration, ~4  
43  
44 201 g D2O) was administered as a fixed dose. Saliva samples were collected at hourly  
45  
46 202 intervals (3,4 and 5 hours) in a sample of 42 children (well-nourished recovering from  
47  
48 203 MAM=13; MAM n=22; SAM=7) aged 7-30 months. Since our aim was to determine  
49  
50 204 equilibration time, we included in our analysis children who spilled some of the dose,  
51  
52 205 because while this would negate accurate calculation of body water, it would not  
53  
54 206 prevent assessment of equilibration time.  
55  
56  
57  
58  
59  
60

1  
2  
3 207 **2.3 Statistics**

4  
5 208 Data were double entered in Epidata 3.1 (Odense, Denmark). Descriptive  
6  
7 209 summary measures (percentage, mean +/- SEM) were used to analyze the data. No  
8  
9 210 formal statistical significance testing was carried out due to limitations in sample size.  
10  
11 211 The statistical software package Stata v12 (StataCorp, College station, Texas, USA)  
12  
13  
14 212 was used.  
15  
16  
17

18 213 **2.4 Ethics**

19  
20 214 This study was approved as part of a larger trial by the Ethics Committee for  
21  
22 215 Health Research in Burkina Faso (2012-8-059) and consultative approval was obtained  
23  
24 216 from the Danish National Committee on Biomedical Research Ethics (1208204).

28 217 **3. Results**

29  
30  
31  
32 218 *Sub-study (a): feasibility of saliva sampling and fluid administration*  
33  
34

35 219 The “cotton ball method” applied in a recent trial in Cambodia, allowing a child  
36  
37 220 to suck on a cotton ball with a tied-on thread hanging out the mouth hold by the  
38  
39 221 investigator to prevent swallowing, failed in our setting. Children would generally not  
40  
41 222 close their mouths with the cotton-ball inside and too little saliva was collected. On the  
42  
43 223 other hand, the “cotton-stick method”, by which we collected saliva by systematically  
44  
45 224 sweeping the oral cavity, proved effective in collecting our minimum target volume of  
46  
47 225 0.5 ml.  
48  
49

50 226 When administrating fluid directly from a syringe to a child, initially, low  
51  
52 227 acceptability and high levels of spillage were encountered. Consequently, a number of  
53  
54 228 alternative techniques were investigated: a number of local cups were found to lead to  
55  
56 229 excessive spillage both when applied by investigators and mothers. In healthy children  
57  
58  
59  
60

1  
2  
3 230 there was a tendency of better acceptance when drinking fluid from a baby bottle. But in  
4  
5 231 children with MAM there was generally little will to suck from the baby bottle. Making  
6  
7 232 sucking easier by increasing the size of the hole in the teat led to excessive spillage. In  
8  
9 233 healthy children a well-known local drink, Bissap (sugary and containing hibiscus), was  
10  
11 234 well accepted when tested as dilution. Bissap being red in colour also made it possible  
12  
13 235 to discriminate between spillage from pure saliva and spillage from diluted  $^2\text{H}_2\text{O}$ .  
14  
15  
16 236 However, when tested in children with MAM, Bissap was not better accepted than  
17  
18 237 water. We identified no better way to administrate fluid than by disposable syringes.  
19  
20

21  
22 238 *Sub-study (b): the effects of adding of sugar to the dose solution*  
23

24  
25 239

26 240 Testing the addition of sucrose, in the laboratory setting, led to a large  
27  
28 241 interfering peak which altered the appearance of the O-D stretch, and affected the  
29  
30 242 calculation of  $^2\text{H}_2\text{O}$  abundance. A known standard of 1184 ppm of  $^2\text{H}_2\text{O}$  mixed with  
31  
32 243 sucrose as a 10% solution resulted in a higher observed isotope abundance of  $1560 \pm 1$   
33  
34 244 ppm.  
35  
36

37  
38 245

39  
40  
41 246 *Sub-study (c): fractionation bias in collecting saliva*  
42

43  
44 247 We show the differences in the adult post dose saliva (Es) isotopic abundances  
45  
46 248 collected with mouth closed and mouth open in **Table 1**. To estimate consequences for  
47  
48 249 these differences in post-dose isotopic abundances relevant to our paediatric population  
49  
50 250 we calculated dilution space, N, with hypothetical values for  $\text{TA}/a=5000$ ,  $\text{Ed}-\text{Et}=1000$ ,  
51  
52 251  $\text{Ep}=96$ . These calculated differences in dilution space were considerable, ranging from -  
53  
54 252 4 to 7%.  
55  
56

57  
58 253  
59  
60

1  
2  
3 254 *Sub-study (d): evaporation through dose spillage*

4  
5 255 There was a 31% (SEM 3) evaporation of diluted  $^2\text{H}_2\text{O}$  from gauzes across  
6  
7 256 experimental conditions in this sub-study. Details on results of the experiments are seen  
8  
9 257 in **Table 2**.

10  
11  
12  
13 258 *Sub-study (e): precision of dosing isotope abundance determination from stock*  
14  
15 259 *solution*

16  
17 260 As seen in **Table 3** we found up to 8% difference in isotope abundance  
18  
19  
20 261 determination in samples from same DDS solution measured on different occasions.

21  
22  
23 262 *Sub-study (f): Equilibration time*

24  
25 263 The children had an average weight of 7.3 kg (SEM 0.2) (range 4.81-9.8).

26  
27 264 Baseline saliva was successfully obtained in 39 of 42 children (93%) with a mean saliva  
28  
29 265 volume of 1 ml (SEM 0.06). Three children failed to produce baseline saliva due to  
30  
31 266 crying and dry mouths and were taken out of the study. In two children the dose was not  
32  
33 267 given due to crying and these children were taken out of the study. Samples from one  
34  
35 268 child were lost.

36  
37  
38 269 In the 36 remaining children all post-dose saliva samples were successfully  
39  
40 270 collected. Equilibrium was reached at three hours as seen in **Figure 2** as abundance of  
41  
42 271 deuterium in saliva (Panel A) or calculations of TBW (Panel B). In the vast majority of  
43  
44 272 children there was a clear pattern. From three hours onwards, subsequent total body  
45  
46 273 waters were either essentially static (defined a change of  $<0.1$  kg TBW) or rising  
47  
48 274 slightly. All of these subjects indicated equilibration of isotope by three hours. In four  
49  
50 275 children a pattern was found with a rise in TBW (fall in isotope abundance) from three  
51  
52 276 to four hours followed by a rise from four to five hours. We suspect these findings to be  
53  
54 277 artefacts possibly being caused by a large drink between three and four hours. One child  
55  
56  
57  
58  
59  
60

1  
2  
3 278 showed three very different values, the highest value at 4 hours, and we suspect an  
4  
5 279 irregularity with drinking (e.g. in the period prior to 3 hours), or saliva sampling (e.g.  
6  
7 280 evaporation/fractionation at 1 or more time points) or both.  
8  
9

#### 10 281 **4. Discussion**

11  
12  
13 282 Prior to a randomized trial we conducted a pilot to adapt and develop the  
14  
15 283 deuterium dilution technique specifically for use in children with MAM and a hot  
16  
17 284 climate and rural setting. Our findings and considerations may be of wider use for field  
18  
19 285 studies in undernutrition considering body composition as an outcome.  
20  
21  
22

##### 23 286 **4.1 Saliva collection**

24  
25 287 We developed a cotton-stick method that ensured a high success rate of >90%  
26  
27 288 for saliva collection. Likewise, we established that **isotope abundances** of post-dose  
28  
29 289 saliva samples were determined differently if collected with an open mouth compared to  
30  
31 290 a closed mouth, possibly related to fractionation, and we recommend that saliva is  
32  
33 291 collected while the mouth of the child is gently kept closed. We decided for the trial to  
34  
35 292 drape the saliva collection environment with a cloth, to protect the process from direct  
36  
37 293 sunlight and also to minimise risk of fractionation. At the time of our pilot the FTIR  
38  
39 294 equipment used required ~0.5 ml per analysis, hence ~1 ml per duplicate **isotope**  
40  
41 295 **abundance** determination. Newer FTIR systems allow duplicate analysis of as little as  
42  
43 296 60 microliters which will ease the collection of sample material for future trials. To  
44  
45 297 minimise risk of contamination of saliva samples, we physically separated the location  
46  
47 298 for dosing and saliva collection. In addition, a 30 minutes fasting period saliva before  
48  
49 299 sampling was requested including breastfeeding.  
50

57  
58  
59  
60

1  
2  
3 301 **4.2 Dose and administration**

4 302 When running a large trial, it is important to simulate what the highest and  
5  
6 303 lowest **isotope abundance** would be from putting the same dose into a small and a large  
7  
8 304 child. If the child was very big, the post-dose enrichment would be low; if the child was  
9  
10 305 small, the dose would be high. It depends what range of **isotope** abundances the FTIR  
11  
12 306 lab are able to cover.

13  
14  
15 307 We used diluted  $^2\text{H}_2\text{O}$  for dosing, as undiluted  $^2\text{H}_2\text{O}$  may lead to inaccuracy of  
16  
17 308 estimation of dose ingested by child.  $^2\text{H}_2\text{O}$  is enriched relative to water vapor in the air  
18  
19 309 and will fractionate rapidly. The risk is that not all the dose swallowed and evaporates  
20  
21 310 off the surface of the mouth and throat. With a dose of 5 g isotope, a loss of 0.05 g in  
22  
23 311 this way will result in a 1% dosing error, i.e. a 1% body water error. In the same way,  
24  
25 312 scales weighing accurate to at least 0.01 g are necessary to minimize error on the  
26  
27 313 calculated mass of dose administered.

28  
29 314 By diluting the dose with potable water, the relative error of evaporation will be  
30  
31 315 reduced. The magnitude of dilution of the dose is influenced by both biological and  
32  
33 316 practical logistical considerations. To cover all weight ranges in our trial and to make  
34  
35 317 logistics as easy as possible for the trial, all children received 5 g  $^2\text{H}_2\text{O}$  in about 10 mL  
36  
37 318 DDS, meaning that the total dose to be consumed was ~10 mL.

38  
39 319 When running a large trial it is tempting to reduce the workload by determining  
40  
41 320 **isotope abundance** in the DDS solutions and use this value for all children having  
42  
43 321 received an aliquot from this solution. However, in this pilot we established substantial  
44  
45 322 variability in samples from same DDS aliquoted on different time points. Subsequently,  
46  
47 323 we decided for our main trial to analyse isotopic **abundance** in every individual dose  
48  
49 324 given **a so-called individual study dose (ISD)**.

50  
51 325 We tested various techniques for dosing, and ended up with the conventional use  
52  
53 326 of disposables syringes. Likewise, we had to abandon the idea of adding a local flavour  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 327 to the dose as the sugar content in the local drink identified would have interfered with  
4  
5 328 **isotope abundance** analysis in FTIR analysis. For studies analysing samples on mass  
6  
7 329 spectrometry the addition of sugar would still be an option. However, from a logistical  
8  
9 330 point of view using disposable material and plain water as diluent makes a large study  
10  
11 331 more feasible. We established that in the local setting evaporation takes place extremely  
12  
13 332 fast with the risk of overestimation of dose in child. For our trial we made procedures to  
14  
15 333 minimize time dose was exposed to environment and to instantly place gauze with  
16  
17 334 spillage into airtight containers.  
18  
19  
20  
21

22 335 We established that equilibration time **in saliva** in local context is 3 hours,  
23  
24 336 **just a few children diverted from this pattern which we consider was probably**  
25  
26 337 **related to the ingestion of large drinks** during the equilibration period. Previous  
27  
28 338 work in younger age groups has been conducted on healthy subjects in high  
29  
30 339 income settings. Most work on infants has used a "back extrapolations" method  
31  
32 340 [16] to calculate body water. This uses repeat post-dose urine samples across  
33  
34 341 several days, since body water was typically calculated as part of the doubly  
35  
36 342 labelled water method for estimation of energy expenditure. Other studies of  
37  
38 343 infants, children and adults suggest that isotopic equilibration typically occurs **in**  
39  
40 344 **saliva** within three hours [22,23], however a longer period may be required for  
41  
42 345 those overweight. No information is available on the time required for  
43  
44 346 equilibration in undernourished children.  
45  
46  
47  
48

49 347 Furthermore, as some children during dosing would spit in a manner or degree  
50  
51 348 that could not be collected by gauze, we decided for our trial to include estimation of  
52  
53 349 dose loss if administration was not perfect. Also to avoid the risk of children vomiting  
54  
55 350 after the dosing we imposed an observation period following dose administration.  
56  
57  
58  
59  
60

1  
2  
3 351 During our trial we improved the psycho-social environment by using only experienced  
4  
5 352 local staff and creating a playful/calm atmosphere.  
6

7 353

8  
9 354 The experiences from our pilot study led to development of standard operational  
10  
11 355 procedures for management of the deuterium dilution techniques in our trial that can be  
12  
13 356 found as online supplemental material. *Online supplemental material 1: Laboratory*  
14  
15 357 *Deuterium oxide* dilution, Sampling and Aliquoting. *Online supplemental material 2:*  
16  
17 358 *Dose* administration in field and *Online supplemental material 3: Field data collection*  
18  
19 359 sheet.  
20  
21

22  
23 360 A limitation of our study is that we did not propagate our raw isotopic data to  
24  
25 361 body water values and hence body composition, which would potentially have allowed  
26  
27 362 us to assess the overall accuracy of the deuterium technique relative to a reference body  
28  
29 363 composition method (eg air-displacement plethysmography). We did not have access to  
30  
31 364 any such reference method in this field setting. Such a validation study would be a  
32  
33 365 valuable future aim. Nevertheless our work reported here has clarified how to optimise  
34  
35 366 the protocol for collecting isotopic data in children with moderate acute malnutrition.  
36  
37  
38  
39

## 40 367 **5. Conclusion**

41  
42  
43 368 We established how to collect saliva and dose diluted  $^2\text{H}_2\text{O}$  in a local Burkinabe  
44  
45 369 setting prior to a large intervention study in children with MAM. Our pilot findings and  
46  
47 370 standard operating procedures developed for the main trial may be of wider use for  
48  
49 371 groups considering using the deuterium dilution technique in malnutrition studies in  
50  
51 372 field conditions. However, we encourage that a local pilot is always undertaken prior to  
52  
53 373 the application of this method.  
54  
55  
56  
57

7	730	724	-7	634	628	7880	7967	87	1.1

Es1 is **isotope abundance** of saliva collected with mouth closed. Es2 is **isotope abundance** of saliva collected with open mouth. To calculate dilution space N hypothetical values were used for  $TA/a=5000$ ,  $Ed-Et=1000$ ,  $Ep=96$  (not shown in table)

Table 2: Effect of evaporation of spillage

<u>Experiments</u>	<u>%Δ weight (SEM)</u>
a. Gauze touching skin, 3 min	25 (8)
b. Gauze touching skin, 7 min	36 (3)
c. Loose gauze, 3 min	22 (2)
d. Loose gauze, 7 min	39 (3)

Percentage weight loss of ~ 1 g of diluted  $^2\text{H}_2\text{O}$ . Determined in triplicate measurements in each of a-d

Table 3: Accuracy in dosing **abundance** determination from **diluted deuterium oxide** stock solution

DDS #	Day #	A	twdil(g)	a (g)	Ed	Es-Ep	TA/a	N	%ΔN
1	1	10	49.9	0.106	816.3	1000	4699	5756.3	-
1	2	10	49.4	0.101	794.5	1000	4903	6171.3	7.2

2	1	10	49.1	0.100	799.7	1000	4906	6135.4	-
2	2	10	49.3	0.102	804.9	1000	4834	6004.8	-2.1
2	5	10	48.9	0.103	820.7	1000	4771	5813.7	-5.2

DDS# indicates which of two **diluted deuterium oxide stocks** that was sampled. Day indicates day of sampling. Twdil is the mass of tap water used to analyse the DDS while a is the mass of DDS used to analyse **isotope abundance**. Ed is the determined dose **abundance**, while A, Es-Ep, TA/a are hypothetical values to calculate the dilution space in a child similar to our study population.

*ONLINE SUPPLEMENTAL MATERIAL 1***Laboratory Deuterium oxide dilution, Sampling and Aliquoting****Preparation of DDS-batch**

A Diluted Deuterium oxide Stock (DDS) is prepared by mixing bottled-water (brand: Lafi) and 99.8% D2O (brand: Cambridge Isotope). Mix DDS in a clean 1 L borosilicate bottle with a PTFE facing disc screw cap (mixing-bottle). Weigh on an electronic scale (range: 0-2 kg (0.1 g)). Keep lids on bottles during weighing to diminish evaporation.

- a) Calibrate weight. Check against a standard object.
- b) Tare bottle + lid (to 0.1 g).
- c) Dispense ~ 450 mL 99.8% D2O to mixing-bottle using a glass cylinder.
- d) Weigh D2O in the mixing-bottle (~ 500 g) and record exact weight in the DDS-log
- e) Add ~ 500 mL of bottled-water to the mixing bottle using a glass cylinder.
- f) Weigh what is now a new DDS (~ 1000 g) and record exact weight in the DDS-log.
- g) Mix DDS thoroughly by systematically turning mixing-bottle upside down 15 times before sampling and aliquoting.

Every new DDS is assigned a unique DDS-code: *T-DDS-##*. Where ## is a new consecutive number.

- a) When dispensing with new pipette tip DDS must be drawn back and forth 5 times to saturate the plastic pipette tip with D2O.
- b) For every new DDS collect a ~2 ml sample (from the middle of the mixing-bottle) in a cryotube with O-ring. Label with *T-DDS-##* and store at -20°.

Data to register in the physical DDS-log book and electronically	Date	<i>T-DDS-##</i>	Weight D2O	Weight DDS

**Preparation of Dose-Bottles**

12 ml DDS is out-portioned in a Dose-Bottle (10 ml = Individual Study Dose (ISD) will be administered to study participant; the additional 2 ml = ISD-sample will establish the exact abundance of D2O in Dose-Bottle). One DDS is enough for ~ 78 Dose-bottles.

- c) Dispense exactly 12 ml DDS by using a pipette into a Dose-Bottle that is immediately closed.
- d) Add label on the Dose-Bottle with: *T-DDS-##*.
- e) After Aliquoting 10 Dose-Bottles mix remaining DDS thoroughly by systematically turning mixing-bottle upside down 15 times.
- f) Place Dose-Bottle in fridge (4°C) in until field usage.

**Logistics**

1  
2  
3  
4 DDS is mixed and Dose-bottles prepared according to field needs and kept in fridge (4°C). 1 DDS  
5  
6 contains a volume for ~ 78 Dose-Bottles (if field needs are small freeze half the Dose-Bottles).  
7

8  
9 Every morning Dose-bottles are transported from lab to field-sites in a cold bag. Unused Dose-  
10  
11 bottles are returned to fridge in lab every evening and a dot is added to the label indicating a "day-  
12  
13 in-the-field". Dose-Bottle with most dots should be used first in field. However, Dose-Bottles with  
14  
15 five dots must be thrown out.  
16  
17

18  
19 **Background for choosing 5 g D20:**

20 In TreatFood children aged 6-23 months with MAM are included. Intervention is for 3 months. An  
21 **ISD** is administered at t=0 and t=3 months. Gross Estimation of weight range: 5.1-12.5 kg (6  
22 months-old- girls -3SD/ 26 months-old-boy **median** (based on weight-for-height WHO  
23 standards)).

24 The proportion of water in the body varies in relation to fatness. In thin children, lean mass can be  
25 >90% of the weight and if hydration of lean tissue were 78%, around 70% of weight could be  
26 water - possibly even more as malnutrition can lead to water retention. With 5 g of D20 and an  
27 hydration of body mass of 70 % the estimated range of enrichment according to weight range will  
28 be 5 g D20/(weight \*.7)= ~570-1400 ppm.  
29

30  
31 **Background for DDS mixing D20 dilution:**

32 Calculations made on the assumption that temperature is 25 C°

33 Density D2O: 1.105 g/mL

34 Density H2O: 0.997 g/mL  
35

36 **Characteristics of one DDS:**

37 Volume: 950 ml (450 ml D2O + 500 ml H2O)

38 Weight: 995 gr (497 gr D2O + 498 gr H2O)

39 Weight proportion D2O/DDS ~ 0,5

40 1 mL of DDS weighs: ~ 1.048 gr

41 1 mL of DDS contains : ~ 0.523 gr D2O (1.048 gr \* 0.5)  
42  
43

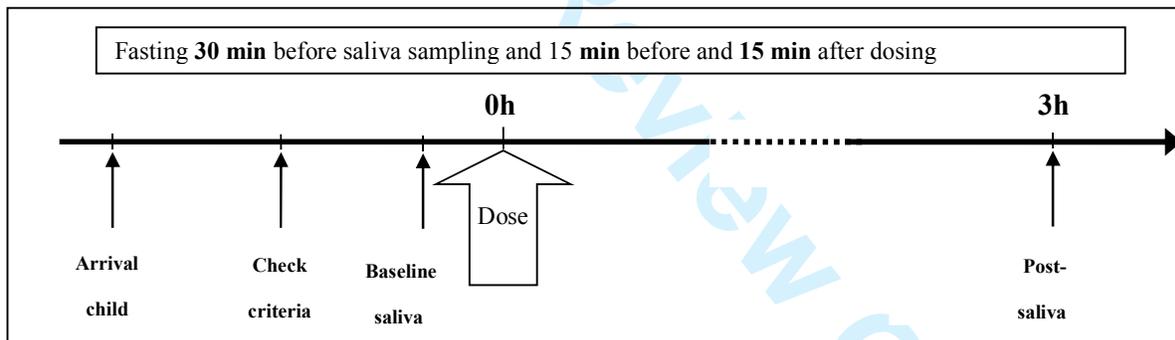

44 **5 gr D2O in: ~ 10 mL DDS** or Precisely 9.56 ml DDS (5 gr D2O/0.523 gr D2O/ml DDS)

## ONLINE SUPPLEMENTAL MATERIAL 2

**Dose administration in field**

A successful **dose** administration is: When the **precise** weight of D<sub>2</sub>O swallowed by child is known and when 0.5-1 ml of saliva has been collected before and after dosing.

The method takes time, precision and patience! Procedures must never be rushed and a child-friendly environment must at all times be maintained. Activities are separated in three different locations in field: Observation (OBS), Saliva sampling (SAL) and dosing (**DOSE**). All information must be meticulously recorded according to the Deuterium Data Collection Sheet of individual children and in a general Deuterium Field Logbook. The Electronic balance is calibrated every morning and precision tested with an object of known weight.

**Overview:****1) Checking criteria and observing fasting before baseline saliva sampling (OBS)**

- Check criteria: child must have passed registration and anthropometry.
- Observe that child is fasting 30 minutes prior to saliva sampling.
- Make sure Deuterium Data Collection Sheet is correctly filled in.

**2) Baseline saliva sampling (SAL)**

- Confirm that child has been fasting 30 min prior to baseline saliva sampling.
- Mark (with pen) a 2 ml cryotube with o-ring and red cap with study-ID of child: T#####.
- Explain procedure to caretaker.
- Wipe the mouth of the child with dispensable paper tissue before start.

- 1  
2  
3  
4 e) Wear new dry gloves before collection. Any kind of fluid on fingers can contaminate results.  
5  
6 f) Collect saliva out of bright sunlight with an already prepared cotton-stick<sup>1</sup>. Systematically collect  
7 saliva with cotton stick with one hand while the other hand gently closes the mouth of the child. Two  
8 persons might be needed.  
9  
10 g) When first cotton stick is introduced in child's mouth start clock to time collection time.  
11  
12 h) Remove the cotton now soaked with saliva from cotton stick and extract saliva using the plunger  
13 from a new 10 ml syringe into cryotube. **Close the lid well immediately.**  
14  
15 i) It is often necessary to repeat collection procedure a number of times to obtain sufficient saliva.  
16  
17 j) Target volume is 1 ml. Absolute minimum volume is 0,5 ml.  
18  
19 k) As long as volume of 0.5 ml saliva has not been reached collection must be continued. If 0.5 ml  
20 saliva or more has been collected after 10 minutes collection is discontinued. (NB: it should be a  
21 very rare situation if collection of saliva must be given up before reaching 0.5 ml)  
22  
23 l) The same 10 ml syringe and plunger can be used for same saliva sample. If syringe is polluted a new  
24 syringe is needed. While collecting saliva the syringe is placed on a clean paper tissue. Paper tissues  
25 are changed if wet and always between children.  
26  
27 m) Label cryotube with pre-printed labels: At inclusion T####-S-ZERO-IN and at 3 months T####-S-  
28 ZERO-EX.  
29  
30 n) Immediately place baseline saliva sample in small zip locked plastic bag placed in "low abundance"  
31 cold bag (4°C). All small bags of baseline saliva sampling are collected in a big zip locked bag to  
32 separate baseline from post dose saliva samples.  
33  
34 o) Discard cotton-sticks, syringe and gloves.  
35  
36 p) Make sure Deuterium Data Collection Sheet is correctly filled in.  
37  
38  
39 **3) Observe fasting before dosing (OBS)**  
40  
41 a) Child must be confirmed fasting for min. 15 min prior to dosing  
42  
43 b) Make sure Deuterium Data Collection Sheet is correctly filled in.  
44  
45 **4) Deuterium dosing (DOSE)**  
46  
47 a) Carefully note all results continuously as indicated on the *Deuterium data collection form*.  
48  
49 b) Confirm that child has been fasting 15 min. prior to dose administration.  
50  
51 c) Label a 2 ml cryotube with o-ring and yellow cap: T####-ISD-IN and at 3 months T####-ISD-EX.  
52  
53 d) Explain caretaker procedure and allow time to play and interact with child.

---

54 <sup>1</sup> Cotton sticks are prepared with an extra layer of cotton. Cotton sticks must be prepared wearing new gloves  
55 and away from the daily activities in the hangar to avoid contamination with D2O.  
56  
57  
58  
59  
60

- 1  
2  
3  
4 e) Wear new gloves. Get Dose-Bottles with DDS from cold bag. Always first use Dose-Bottles with  
5 most "field-days" indicated on label.  
6  
7 f) Mix by turning Dose-Bottle upside-down systematically 15 times.  
8  
9 g) Draw 10 ml of DDS into a new 10 ml syringe using a 19G needle. The content in the syringe is now  
10 an individual study dose (ISD). If syringe is not completely dry on outside wipe with paper tissue  
11 that is immediately disposed.  
12  
13 h) Place the full syringe in a sealed plastic bag together with 5 new pieces of gauze. Make sure no fluid  
14 is squeezed out of syringe while handling.  
15  
16 i) With a single use plastic pipette dispense the remaining approx. 2 mL from the Dose-Bottle into a  
17 labelled cryo-tube. Dispose the pipette after use.  
18  
19 j) All ISD samples from same day are placed in a small zip plastic bag. ISD samples have a high  
20 concentration of D2O and must never be stored with saliva samples. ISD sample are placed in "high  
21 **abundance**" cold bag (4°C) also used for Dose-Bottles.  
22  
23 k) Place plastic container on scale and Tare scale. Place plastic bag with content in plastic container.  
24 Make sure that plastic bag is completely inside the plastic container. Weigh plastic bag with content  
25 with two decimals precision.  
26  
27 l) Dry the infant around the mouth with a paper tissue before dosing is initiated. Dispose tissue.  
28  
29 m) Be prepared for collecting any ISD spillage during administration on the pre-weighed tissues  
30 (gauzes). Pure drooling to be collected on disposable paper tissue.  
31  
32 n) Administer ISD slowly and precisely in the corner of the mouth. Collect ISD spillage on gauze. Wet  
33 gauze is placed in plastic bag and replaced with a dry piece of gauze. Plastic bag is always kept  
34 closed. 2 persons will often be needed for the procedure.  
35  
36 o) If 5 pieces of gauze is not sufficient extra gauze (that has been pre-weighed) are used.  
37  
38 p) After administration tare scale with plastic container. Place plastic bag with all content previously  
39 being weighed (ISD syringe + 5 pieces of gauze) in container and re-weigh. Note result on *data*  
40 *collection form*. If extra gauze has been used the procedure is repeated here. The difference in weight  
41 of bag with content before and after administration = weight of **dose** in child.  
42  
43 q) Note the exact time of end of dosing in *data collection form*.  
44  
45 r) Discard gloves and all material used.  
46  
47  
48  
49  
50 **5) Post dosing observation (OBS)**  
51 a) The child must be observed 15 min post dose fasting. If the child is regurgitating in this time period  
52 it should be noted in the *data collection form*.  
53  
54  
55

56 **6) Observing fasting before post dose saliva sampling (OBS)**  
57  
58  
59  
60

- 1  
2  
3  
4 a) The child must be observed fasting 30 min. before post dose saliva sample.  
5 b) Make sure Deuterium Data Collection Sheet is correctly filled in.  
6  
7

8  
9 **7) Post dose saliva sampling (SAL)**

- 10 a) Starting exactly 3 hours after completion of D2O dosing the post dose saliva sample is collected  
11 following exactly the same steps as for baseline saliva collection. Use cryotube with o-ring and  
12 green cap. Label Post dose saliva sample T#####-S-POST-IN and at 3 months T#####-S-POST-EX  
13  
14 b) Immediately place post dose saliva sample in small zip locked plastic bag placed in "low abundance"  
15 cold bag (4°C). All small bags of post dose saliva sampling are collected in a big zip locked bag to  
16 separate baseline from post dose saliva samples.  
17  
18

19  
20  
21 **8) Central Lab**

- 22 a) At the end of the day all samples are transported to central lab in cold bags and as fast as possible  
23 frozen (-20°C) until analysis to minimise bacterial growth  
24

25 **9) Cotton stick preparation**

- 26 a) Cotton sticks are prepared in the morning in the saliva room.  
27  
28 b) 20 cotton sticks are prepared in a new plastic bag. More bags can be prepared at the time.  
29  
30 c) Once removed cotton sticks must not be reintroduced in plastic bag.  
31  
32

33 **Field equipment needed**

<b><u>In field: Saliva sampling</u></b>	<b><u>In field: Administration/sampling of D2O</u></b>
Cotton sticks with extra cotton	Electronic balance (precision 0.01)
10 ml syringes	10 mL syringes
Disposable paper tissues	Zip-lock plastic bag
2 ml cryotubes with labels	19 G needle
Gloves	Safety box for disposed needles
Zip-lock plastic bag	2 ml cryotubes with labels
Stop watch	Disposable paper tissues
Cold-chain	Gaze-tissue approx. 7.5 X 7.5 cm (non-sterile)
	Dose-bottles
